## THE $\rho(1450)$ AND THE $\rho(1700)$

Written March 1998 by S. Eidelman (Novosibirsk) and J. Hernandez (Valencia).

In our 1988 edition, we replaced the  $\rho(1600)$  entry with two new ones, the  $\rho(1450)$  and the  $\rho(1700)$ , because there was emerging evidence that the 1600-MeV region actually contains two  $\rho$ -like resonances. ERKAL 86 had pointed out this possibility with a theoretical analysis on the consistency of  $2\pi$  and  $4\pi$  electromagnetic form factors and the  $\pi\pi$  scattering length. DONNACHIE 87, with a full analysis of data on the  $2\pi$ and  $4\pi$  final states in  $e^+e^-$  annihilation and photoproduction reactions, had also argued that in order to obtain a consistent picture two resonances were necessary. The existence of  $\rho(1450)$ was supported by the analysis of  $\eta\rho^0$  mass spectra obtained in photoproduction and  $e^+e^-$  annihilation (DONNACHIE 87B) as well as that of  $e^+e^- \to \omega\pi$  (DONNACHIE 91).

The analysis of DONNACHIE 87 was further extended by CLEGG 88, 94 to include new data on  $4\pi$  systems produced in  $e^+e^-$  annihilation and in  $\tau$  decays ( $\tau$  decays to  $4\pi$  and  $e^+e^-$  annihilation to  $4\pi$  can be related by the Conserved Vector Current assumption). These systems were successfully analyzed using interfering contributions from two  $\rho$ -like states, and from the tail of the  $\rho(770)$  decaying into two-body states. While specific conclusions on  $\rho(1450) \rightarrow 4\pi$  were obtained, little could be said about the  $\rho(1700)$ .

An analysis by CLEGG 90 of  $6\pi$  mass spectra from  $e^+e^$ annihilation and from diffractive photoproduction provides evidence for two  $\rho$  mesons at about 2.1 and 1.8 GeV that decay strongly into  $6\pi$  states. While the former is a candidate for a new resonance ( $\rho(2150)$ ), the latter could be a manifestation of the  $\rho(1700)$  distorted by threshold effects.

Independent evidence for two 1<sup>-</sup> states is provided by KILLIAN 80 in  $4\pi$  electroproduction at  $\langle Q^2 \rangle = 1$  (GeV/c)<sup>2</sup>, and by FUKUI 88 in a high-statistics sample of the  $\eta\pi\pi$  system in  $\pi^- p$  charge exchange.

This scenario with two overlapping resonances is supported by other data. BISELLO 89 measured the pion form factor in the interval 1.35–2.4 GeV and observed a deep minimum around 1.6 GeV. The best fit was obtained with the hypothesis of  $\rho$ -like resonances at 1420 and 1770 MeV with widths of about 250 MeV. ANTONELLI 88 found that the  $e^+e^- \rightarrow \eta \pi^+ \pi^-$  cross section is better fitted with two fully interfering Breit-Wigners, with parameters in fair agreement with those of DONNACHIE 87 and BISELLO 89. These results can be considered as a confirmation of the  $\rho(1450)$ .

Decisive evidence for the  $\pi\pi$  decay mode of both  $\rho(1450)$ and  $\rho(1700)$  came from recent results in  $\overline{p}p$  annihilation at rest (ABELE 97). According to ABELE 98 these resonances also possess a  $K\overline{K}$  decay mode. High statistics studies of the  $\tau \to \pi\pi\nu_{\tau}$  decay also require the  $\rho(1450)$  (BARATE 97M, URHEIM 97), but are not sensitive to the  $\rho(1700)$  because it is too close to the  $\tau$  mass.

The structure of these  $\rho$  states is not yet completely clear. BARNES 97 and CLOSE 97C claim that  $\rho(1450)$  has a mass consistent with radial 2S, but its decays show characteristics of hybrids and suggest that this state may be a 2S-hybrid mixture.

We also list under the  $\rho(1450)$  the  $\phi\pi$  state with  $J^{PC} = 1^{--}$ or C(1480) observed by BITYUKOV 87. While ACHASOV 96B shows that it may be a threshold effect, CLEGG 88 and LANDSBERG 92 suggest two independent vector states with this decay mode. Note, however, that C(1480) in its  $\phi\pi$  decay mode was not confirmed by  $e^+e^-$  (DOLINSKY 91, BISELLO 91C) and  $\overline{p}p$  (ABELE 97H) experiments.

Several observations on the  $\omega\pi$  system in the 1200-MeV region (FRENKIEL 72, COSME 76, BARBER 80C, ASTON 80C, ATKINSON 84C, BRAU 88, AMSLER 93B) may be interpreted in terms of either  $J^P = 1^- \rho(770) \rightarrow \omega\pi$  production (LAYSSAC 71) or  $J^P = 1^+ b_1(1235)$  production (BRAU 88, AMSLER 93B). We argue that no special entry for a  $\rho(1250)$  is needed. The LASS amplitude analysis (ASTON 91B) showing evidence for  $\rho(1270)$  is preliminary and needs confirmation. For completeness, the relevant observations are listed under the  $\rho(1450)$ .
