

$$J = \frac{1}{2}$$

The following results are obtained using neutrinos associated with μ^+ or μ^- . See Note on "Neutrino Mass," to be published in the PDG www update of November 2001.

ν MASS

In the context of some models, it is possible that this weighted sum over mass eigenstates is the same as for the neutrinos produced in τ decay.

In some of the ASTR and COSM papers listed below, the authors did not distinguish between weak and mass eigenstates.

OUR EVALUATION is based on OUR AVERAGE for the π^\pm mass and the ASSAMAGAN 96 value for the muon momentum for the π^+ decay at rest. The limit is calculated using the unified classical analysis of FELDMAN 98 for a Gaussian distribution near a physical boundary. WARNING: since m_ν^2 is calculated from the differences of large numbers, it and the corresponding limits are extraordinarily sensitive to small changes in the pion mass, the decay muon momentum, and their errors. For example, the limits obtained using the JECKELMANN 94, LENZ 98, and the weighted averages are 0.15, 0.29, and 0.19 MeV, respectively.

VALUE (MeV)	CL%	DOCUMENT ID	TECN	COMMENT

<0.3		⁴ FULLER	91 COSM	Nucleosynthesis
<0.42		⁴ LAM	91 COSM	Nucleosynthesis
<0.50	90	⁵ ANDERHUB	82 SPEC	$m_\nu^2 = -0.14 \pm 0.20$
<0.65	90	CLARK	74 ASPK	$K_{\mu 3}$ decay

¹ ASSAMAGAN 96 measurement of p_μ from $\pi^+ \rightarrow \mu^+ \nu$ at rest combined with JECKELMANN 94 Solution B pion mass yields $m_\nu^2 = -0.016 \pm 0.023$ with corresponding Bayesian limit listed above. If Solution A is used, $m_\nu^2 = -0.143 \pm 0.024 \text{ MeV}^2$. Replaces ASSAMAGAN 94.

² DOLGOV 95 removes earlier assumptions (DOLGOV 93) about thermal equilibrium below T_{QCD} for wrong-helicity Dirac neutrinos (ENQVIST 93, FULLER 91) to set more stringent limits.

³ ENQVIST 93 bases limit on the fact that thermalized wrong-helicity Dirac neutrinos would speed up expansion of early universe, thus reducing the primordial abundance. FULLER 91 exploits the same mechanism but in the older calculation obtains a larger production rate for these states, and hence a lower limit. Neutrino lifetime assumed to exceed nucleosynthesis time, $\sim 1 \text{ s}$.

⁴ Assumes neutrino lifetime $> 1 \text{ s}$. For Dirac neutrinos only. See also ENQVIST 93.

⁵ ANDERHUB 82 kinematics is insensitive to the pion mass.

$m_\nu - m_{\bar{\nu}}$

Test of *CPT* for a Dirac neutrino. (Not a very strong test.)

⁶ KRAKAUER 91 quotes the limit $\tau/m_{\nu_1} > (0.75a^2 + 21.65a + 26.3) \text{ s/eV}$, where a is a parameter describing the asymmetry in the neutrino decay defined as $dN_\gamma/d\cos\theta = (1/2)(1 + a\cos\theta)$. The parameter $a=0$ for a Majorana neutrino, but can vary from -1 to 1 for a Dirac neutrino. The bound given by the authors is the most conservative (which applies for $a = -1$).

⁷ BILLER 98 use the observed TeV γ -ray spectra to set limits on the mean life of a radiatively decaying neutrino between 0.05 and 1 eV. Curve shows $\tau_\nu/B_\gamma > 0.15 \times 10^{21} \text{ s}$ at 0.05 eV, $> 1.2 \times 10^{21} \text{ s}$ at 0.17 eV, $> 3 \times 10^{21} \text{ s}$ at 1 eV, where B_γ is the branching ratio to photons.

⁸ BLUDMAN 92 sets additional limits by this method for higher mass ranges. Cosmological limits are also obtained.

⁹ Nonobservation of γ 's in coincidence with ν 's from SN 1987A. Results should be divided by the $\nu \rightarrow \gamma X$ branching ratio.

¹⁰ DODELSON 92 range is for wrong-helicity keV mass Dirac ν 's from the core of neutron star in SN 1987A decaying to ν 's that would have interacted in KAM2 or IMB detectors.

- 11 CHUPP 89 should be multiplied by a branching ratio (about 1) and a detection efficiency (about 1/4), and pertains to radiative decay of any neutrino to a lighter or sterile neutrino.
 12 Model-dependent theoretical analysis of SN 1987A neutrinos.
 13 Limit applies to ν_τ also.
 14 These experiments look for $\nu_k \rightarrow \nu_j \gamma$ or $\bar{\nu}_k \rightarrow \bar{\nu}_j \gamma$.
 15 HENRY 81 uses UV flux from clusters of galaxies to find $\tau > 1.1 \times 10^{25}$ s for radiative decay.
 16 KIMBLE 81 uses extreme UV flux limits to find $\tau > 10^{22-10^{23}}$ s.
 17 REPHAELI 81 consider the effect of radiative neutrino decay on neutral H in early universe based on M31 HI. They conclude $\tau > 10^{24}$ s.
 18 DERUJULA 80 finds $\tau > 3 \times 10^{23}$ s based on CDM neutrino decay contribution to UV background.
 19 STECKER 80 limit based on UV background; result given is $\tau > 4 \times 10^{22}$ s at $m_\nu = 20$ eV.

ν MAGNETIC MOMENT

Must vanish for a purely chiral massless Dirac neutrino. A massive Dirac or Majorana neutrino can have a transition magnetic moment connecting one mass eigenstate to another one. The experimental limits below usually cannot distinguish between the true (diagonal, in mass) magnetic moment and a transition magnetic moment. The value of the magnetic moment for the standard $SU(2) \times U(1)$ electroweak theory extended to include massive neutrinos (see FUJIKAWA 80) is $\mu_\nu = 3eG_F m_\nu / (8\pi^2 \sqrt{2}) = (3.2 \times 10^{-19}) m_\nu \mu_B$ where m_ν is in eV and $\mu_B = e\hbar/2m_e$ is the Bohr magneton. Given the upper bound $m_\nu < 0.19$ MeV, it follows that for the extended standard electroweak theory, $\mu_\nu < 6 \times 10^{-14} \mu_B$.

²²KRAKAUER 90 experiment fully reported in ALLEN 93.

²³RAFFELT 99 is an update of RAFFELT 90. This limit applies to all neutrino flavors which are light enough (< 5 keV) to be emitted from globular-cluster red giants. This limit pertains equally to electric dipole moments and magnetic transition moments, and it applies to both Dirac and Majorana neutrinos.

²⁴RAFFELT 99 is essentially an update of BERNSTEIN 63, but is derived from the helioseismological limit on a new energy-loss channel of the Sun. This limit applies to all neutrino flavors which are light enough (< 1 keV) to be emitted from the Sun. This limit pertains equally to electric dipole and magnetic transition moments, and it applies to both Dirac and Majorana neutrinos.

²⁵ELMFORS 97 calculate the rate of depolarization in a plasma for neutrinos with a magnetic moment and use the constraints from a big-bang nucleosynthesis on additional degrees of freedom.

²⁶DORENBOSCH 91 corrects an incorrect statement in DORENBOSCH 89 that the ν magnetic moment is $< 1 \times 10^{-9}$ at the 95%CL. DORENBOSCH 89 measures both $\nu_\mu e$ and $\bar{\nu} e$ elastic scattering and assume $\mu(\nu) = \mu(\bar{\nu})$.

²⁷RAFFELT 90 limit applies for a diagonal magnetic moment of a Dirac neutrino, or for a transition magnetic moment of a Majorana neutrino. In the latter case, the same analysis gives $< 1.4 \times 10^{-12}$. Limit at 95%CL obtained from δM_C .

²⁸Significant dependence on details of stellar properties.

²⁹If $m_{\nu} < 10$ keV.

³⁰For $m_{\nu} = 8\text{--}200$ eV. NUSSINOV 87 examines transition magnetic moments for $\nu_{\mu} \rightarrow \nu_e$ and obtain $< 3 \times 10^{-15}$ for $m_{\nu} > 16$ eV and $< 6 \times 10^{-14}$ for $m_{\nu} > 4$ eV.

³¹KIM 74 is a theoretical analysis of $\bar{\nu}_{\mu}$ reaction data.

³²If $m_{\nu} < 1$ keV.

NONSTANDARD CONTRIBUTIONS TO NEUTRINO SCATTERING

We report limits on the so-called neutrino charge radius squared in this section. This quantity is not an observable physical quantity and this is reflected in the fact that it is gauge dependent (see LEE 77C). It is not necessarily positive. A more general interpretation of the experimental results is that they are limits on certain nonstandard contributions to neutrino scattering.
