
 $I^G(J^P) = 1^-(0^-)$

We have omitted some results that have been superseded by later experiments. The omitted results may be found in our 1988 edition Physics Letters **B204** (1988).

π^\pm MASS

The most accurate charged pion mass measurements are based upon x-ray wavelength measurements for transitions in π^- -mesonic atoms. The observed line is the blend of three components, corresponding to different K-shell occupancies. JECKELMANN 94 revisits the occupancy question, with the conclusion that two sets of occupancy ratios, resulting in two different pion masses (Solutions A and B), are equally probable. We choose the higher Solution B since only this solution is consistent with a positive mass-squared for the muon neutrino, given the precise muon momentum measurements now available (DAUM 91, ASSAMAGAN 94, and ASSAMAGAN 96) for the decay of pions at rest. Earlier mass determinations with pi-mesonic atoms may have used incorrect K-shell screening corrections.

Measurements with an error of > 0.005 MeV have been omitted from this Listing.

¹ LENZ 98 result does not suffer K-electron configuration uncertainties as does JECKELMANN 94.

² JECKELMANN 94 Solution B (dominant 2-electron K-shell occupancy), chosen for consistency with positive $m_{\nu_\mu}^2$.

³ ASSAMAGAN 96 measures the μ^+ momentum p_μ in $\pi^+ \rightarrow \mu^+ \nu_\mu$ decay at rest to be 29.79200 ± 0.00011 MeV/c. Combined with the μ^+ mass and the assumption $m_{\nu_\mu} = 0$, this gives the π^+ mass above; if $m_{\nu_\mu} > 0$, m_{π^+} given above is a lower limit.

Combined instead with m_μ and (assuming CPT) the π^- mass of JECKELMANN 94, p_μ gives an upper limit on m_{ν_μ} (see the ν_μ).

⁴ JECKELMANN 94 Solution A (small 2-electron K-shell occupancy) in combination with either the DAUM 91 or ASSAMAGAN 94 pion decay muon momentum measurement yields a significantly negative $m_{\nu_\mu}^2$. It is accordingly not used in our fits.

⁵ The DAUM 91 value includes the ABELA 84 result. The value is based on a measurement of the μ^+ momentum for π^+ decay at rest, $p_\mu = 29.79179 \pm 0.00053$ MeV, uses $m_\mu = 105.658389 \pm 0.000034$ MeV, and assumes that $m_{\nu_\mu} = 0$. The last assumption means that in fact the value is a lower limit.

⁶ JECKELMANN 86B gives $m_\pi/m_e = 273.12677(71)$. We use $m_e = 0.51099906(15)$ MeV from COHEN 87. The authors note that two solutions for the probability distribution of K-shell occupancy fit equally well, and use other data to choose the lower of the two possible π^\pm masses.

⁷ These values are scaled with a new wavelength-energy conversion factor $V\lambda = 1.23984244(37) \times 10^{-6}$ eV m from COHEN 87. The LU 80 screening correction relies upon a theoretical calculation of inner-shell refilling rates.

⁸ This MARUSHENKO 76 value used at the authors' request to use the accepted set of calibration γ energies. Error increased from 0.0017 MeV to include QED calculation error of 0.0017 MeV (12 ppm).

¹⁷ MCFARLANE 85 combines a measured rate $(0.394 \pm 0.015)/s$ with 1982 PDG mean life.

¹⁸ DEPOMMIER 68 says the result of DEPOMMIER 63 is at least 10% too large because of a systematic error in the π^0 detection efficiency, and that this may be true of all the previous measurements (also V. Soergel, private communication, 1972).

$\pi^\pm \rightarrow \ell^\pm \nu \gamma$ AND $K^\pm \rightarrow \ell^\pm \nu \gamma$ FORM FACTORS

Written by H.S. Pruys (Zürich University).

In the radiative decays $\pi^\pm \rightarrow \ell^\pm \nu \gamma$ and $K^\pm \rightarrow \ell^\pm \nu \gamma$, where ℓ is an e or a μ and γ is a real or virtual photon (e^+e^- pair), both the vector and the axial-vector weak hadronic currents contribute to the decay amplitude. Each current gives a structure-dependent term (SD_V and SD_A) from virtual hadronic states, and the axial-vector current also gives a contribution from inner bremsstrahlung (IB) from the lepton and meson. The IB amplitudes are determined by the meson decay constants f_π and f_K [1]. The SD_V and SD_A amplitudes are parameterized in terms of the vector form factor F_V and the axial-vector form factors F_A and R [1–4]:

$$\begin{aligned}
 M(SD_V) &= \frac{-ieG_F V_{qq'}}{\sqrt{2} m_P} \epsilon^\mu \ell^\nu F_V \epsilon_{\mu\nu\sigma\tau} k^\sigma q^\tau , \\
 M(SD_A) &= \frac{-ieG_F V_{qq'}}{\sqrt{2} m_P} \epsilon^\mu \ell^\nu \{F_A [(s-t)g_{\mu\nu} - q_\mu k_\nu] + R t g_{\mu\nu}\} . \\
 \end{aligned} \tag{1}$$

Here $V_{qq'}$ is the Cabibbo-Kobayashi-Maskawa mixing-matrix element; ϵ^μ is the polarization vector of the photon (or the effective vertex, $\epsilon^\mu = (e/t)\bar{u}(p_-)\gamma^\mu v(p_+)$, of the e^+e^- pair); $\ell^\nu = \bar{u}(p_\nu)\gamma^\nu(1 - \gamma_5)v(p_\ell)$ is the lepton-neutrino current; q and k are the meson and photon four-momenta, with $s = q \cdot k$ and $t = k^2 (= (p_+ + p_-)^2)$; and P stands for π or K . In the analysis of data, the s and t dependence of the form factors is neglected, which is a good approximation for pions [2] but not for kaons [4]. The pion vector form factor F_V^π is related via CVC to the π^0 lifetime, $|F_V^\pi| = (1/\alpha)\sqrt{2\Gamma_{\pi^0}/\pi m_{\pi^0}}$ [1]. PCAC relates R to the electromagnetic radius of the meson [2,4], $R^P = \frac{1}{3}m_P f_P \langle r_P^2 \rangle$. The calculation of the other form factors, F_A^π , F_V^K , and F_A^K , is model dependent [1,4].

When the photon is real, the partial decay rate can be given analytically [1,5]:

$$\frac{d^2\Gamma_{P \rightarrow \ell\nu\gamma}}{dxdy} = \frac{d^2(\Gamma_{\text{IB}} + \Gamma_{\text{SD}} + \Gamma_{\text{INT}})}{dxdy} , \quad (2)$$

where Γ_{IB} , Γ_{SD} , and Γ_{INT} are the contributions from inner bremsstrahlung, structure-dependent radiation, and their interference, and the Γ_{SD} term is given by

$$\begin{aligned} \frac{d^2\Gamma_{\text{SD}}}{dxdy} &= \frac{\alpha}{8\pi} \Gamma_{P \rightarrow \ell\nu} \frac{1}{r(1-r)^2} \left(\frac{m_P}{f_P} \right)^2 \\ &\times [(F_V + F_A)^2 \text{SD}^+ + (F_V - F_A)^2 \text{SD}^-] . \end{aligned} \quad (3)$$

Here

$$\begin{aligned} \text{SD}^+ &= (x + y - 1 - r) [(x + y - 1)(1 - x) - r] , \\ \text{SD}^- &= (1 - y + r) [(1 - x)(1 - y) + r] , \end{aligned} \quad (4)$$

where $x = 2E_\gamma/m_P$, $y = 2E_\ell/m_P$, and $r = (m_\ell/m_P)^2$.

In $\pi^\pm \rightarrow e^\pm \nu \gamma$ and $K^\pm \rightarrow e^\pm \nu \gamma$ decays, the interference terms are small, and thus only the absolute values $|F_A + F_V|$ and $|F_A - F_V|$ can be obtained. In $K^\pm \rightarrow \mu^\pm \nu \gamma$ decay, the interference term is important, and thus the signs of F_V and F_A can be obtained. In $\pi^\pm \rightarrow \mu^\pm \nu \gamma$ decay, bremsstrahlung completely dominates. In $\pi^\pm \rightarrow e^\pm \nu e^+ e^-$ and $K^\pm \rightarrow \ell^\pm \nu e^+ e^-$ decays, all three form factors, F_V , F_A , and R , can be determined.

We give the π^\pm form factors F_V , F_A , and R in the Listings below. In the K^\pm Listings, we give the sum $F_A + F_V$ and difference $F_A - F_V$.

The electroweak decays of the pseudoscalar mesons are investigated to learn something about the unknown hadronic structure of these mesons, assuming a standard $V - A$ structure of the weak leptonic current. The experiments are quite difficult, and it is not meaningful to analyse the results using parameters for both the hadronic structure (decay constants, form factors) and the leptonic weak current (*e.g.*, to add pseudoscalar or tensor couplings to the $V - A$ coupling). Deviations from the $V - A$ interactions are much better studied in purely leptonic systems such as muon decay.

| 0.021 ^{+0.011} _{-0.013} | 98 | EGLI | 89 SPEC | $\pi^+ \rightarrow e^+ \nu_e e^+ e^-$ |

25 Using the vector form factor from CVC prediction $F_V = 0.0259 \pm 0.0005$. Only the absolute value of F_A is determined.

26 The result of STETZ 78 has a two-fold ambiguity. We take the solution compatible with later determinations.

π^\pm axial-vector form factor
