

$\Xi(1690)$ $I(J^P) = \frac{1}{2}(\text{??})$ Status: ***

IONISI 78 sees a threshold enhancement in both the neutral and negatively charged $\Sigma\bar{K}$ mass spectra in $K^- p \rightarrow (\Sigma\bar{K})K\pi$ at 4.2 GeV/c. The data from the $\Sigma\bar{K}$ channels alone cannot distinguish between a resonance and a large scattering length. Weaker evidence at the same mass is seen in the corresponding $\Lambda\bar{K}$ channels, and a coupled-channel analysis yields results consistent with a new Ξ .

BIAGI 81 sees an enhancement at 1700 MeV in the diffractively produced ΛK^- system. A peak is also observed in the $\Lambda\bar{K}^0$ mass spectrum at 1660 MeV that is consistent with a 1720 MeV resonance decaying to $\Sigma^0\bar{K}^0$, with the γ from the Σ^0 decay not detected.

BIAGI 87 provides further confirmation of this state in diffractive dissociation of Ξ^- into ΛK^- . The significance claimed is 6.7 standard deviations.

ADAMOVICH 98 sees a peak of 1400 ± 300 events in the $\Xi^-\pi^+$ spectrum produced by 345 GeV/c Σ^- -nucleus interactions.
