		EN detector with <i>u</i>	, fro	m muon	decay at rest and	d obsen

<sup>1</sup>ARMBRUSTER 98 use KARMEN detector with  $\nu_e$  from muon decay at rest and observe  ${}^{12}C(\nu_e, e^-){}^{12}N_{gs}$ . This is a disappearance experiment which is almost insensitive to  $\nu_e \rightarrow \nu_{\mu}$  oscillation. Results are presented as limits to  $\nu_e \rightarrow \nu_{\tau}$  oscillation, although the (non)oscillation could be to a non-visible flavor. A three-flavor analysis is also presented. <sup>2</sup>ASTIER 01B searches for the appearance of  $\nu_{\tau}$  with the NOMAD detector at CERN's SPS. The limit is based on an oscillation probability < 0.74 × 10<sup>-2</sup>, whereas the quoted sensitivity was  $1.1 \times 10^{-2}$ . The limit was obtained following the statitical prescriptions of FELDMAN 98. See also the footnote to ESKUT 01.

<sup>3</sup> ESKUT 01 searches for the appearance of the  $\nu_{\tau}$  with the CHORUS detector at CERN's SPS. The limit is obtained following the statistical prescriptions in JUNK 99. The limit would have been 6 eV<sup>2</sup> if the prescriptions in FELDMAN 98 had been followed, as they were in ASTIER 01B.

#### $\sin^2(2\theta)$ for "Large" $\Delta(m^2)$

 $^4$  ASTIER 01B limit is based on an oscillation probability  $< 0.74 \times 10^{-2}$ , whereas the quoted sensitivity was  $1.1 \times 10^{-2}$ . The limit was obtained following the statitical prescriptions of FELDMAN 98. See also the footnote to ESKUT 01.

<sup>5</sup> ESKUT 01 limit obtained following the statistical prescriptions in JUNK 99. The limit would have been 0.03 if the prescriptions in FELDMAN 98 had been followed, as they  $_{c}$  were in ASTIER 01B.

<sup>6</sup>See foonote in preceding table (ARMBRUSTER 98) for further details, and see the paper for a plot showing allowed regions. A three-flavor analysis is also presented here.

<sup>7</sup> USHIDA 86C published result is  $\sin^2 2\theta < 0.12$ . The quoted result is corrected for a numerical mistake incurred in calculating the expected number of  $\nu_e$  CC events, normalized to the total number of neutrino interactions (3886) rather than to the total number of  $\nu_\mu$  CC events (1870).

 $^{12}$  HAMPEL 98 analyzed the GALLEX calibration results with  $^{51}\mathrm{Cr}$  neutrino sources and updates the BAHCALL 95 analysis result. They also gave 95% and 99% CL limits of < 0.45 and < 0.56, respectively.

<sup>13</sup> BORISOV 96 sets less stringent limits at large  $\Delta(m^2)$ , but exclusion curve does not have clear asymptotic behavior.

$$--- \nu_e \rightarrow (\overline{\nu}_e)_L$$

This is a limit on lepton family-number violation and total lepton-number violation.  $(\overline{\nu}_e)_L$  denotes a hypothetical left-handed  $\overline{\nu}_e$ . The bound is quoted in terms of  $\Delta$  ( $m^2$ ), sin(2 $\theta$ ), and  $\alpha$ , where  $\alpha$  denotes the fractional admixture of (V+A) charged current.

 $^{18}$  AGUILAR 01 is the final analyis of the LSND full data set. Search is made for the  $u_{\mu} \rightarrow \nu_{e} \text{ oscillations using } \nu_{\mu}$  from  $\pi^{+}$  decay in flight by observing beam-on electron events from  $\nu_e C \rightarrow e^- X$ . Present analysis results in 8.1 ± 12.2 ± 1.7 excess events in the  $60 < E_e < 200$  MeV energy range, corresponding to oscillation probability of 0.10 ± 0.16 ± 0.04%. This is consistent, though less significant, with the previous result of ATHANASSOPOULOS 98, which it supersedes. The present analysis uses selection

criteria developed for the decay at rest region, and is less effective in removing the background above 60 MeV than ATHANASSOPOULOS 98.

<sup>19</sup>ATHANASSOPOULOS 98 is a search for the  $\nu_{\mu} \rightarrow \nu_{e}$  oscillations using  $\nu_{\mu}$  from  $\pi^{+}$  decay in flight. The 40 observed beam-on electron events are consistent with  $\nu_{e}C \rightarrow$ 

 $e^-$  X; the expected background is  $21.9\pm2.1$ . Authors interpret this excess as evidence for an oscillation signal corresponding to oscillations with probability  $(0.26\pm0.10\pm0.05)\%$ . Although the significance is only  $2.3\,\sigma$ , this measurement is an important and consistent cross check of ATHANASSOPOULOS 96 who reported evidence for  $\overline{\nu}_{\mu} \rightarrow \overline{\nu}_{e}$  oscillations

from  $\mu^+$  decay at rest. See also ATHANASSOPOULOS 98B.

<sup>20</sup>LOVERRE 96 uses the charged-current to neutral-current ratio from the combined CHARM (ALLABY 86) and CDHS (ABRAMOWICZ 86) data from 1986.

 $^{21}$ LOVERRE 88 reports a less stringent, indirect limit based on theoretical analysis of neutral to charged current ratios.

<sup>22</sup>15ft bubble chamber at FNAL.

<sup>23</sup>AGUILAR 01 is the final analyis of the LSND full data set of the search for the  $\nu_{\mu} \rightarrow \nu_{\rho}$  oscillations. See footnote in preceding table for futher details.

<sup>24</sup> ATHANASSOPOULOS 98 report  $(0.26 \pm 0.10 \pm 0.05)\%$  for the oscillation probability; the value of  $\sin^2 2\theta$  for large  $\Delta m^2$  is deduced from this probability. See footnote in preceding table for further details, and see the paper for a plot showing allowed regions. If effect is due to oscillation, it is most likely to be intermediate  $\sin^2 2\theta$  and  $\Delta m^2$ . See also ATHANASSOPOULOS 98B.

<sup>25</sup> LOVERRE 96 uses the charged-current to neutral-current ratio from the combined CHARM (ALLABY 86) and CDHS (ABRAMOWICZ 86) data from 1986.

 $^{26}$  VILAIN 94C limit derived by combining the  $\nu_{\mu}$  and  $\overline{\nu}_{\mu}$  data assuming CP conservation.

HTTP://PDG.LBL.GOV

Created: 6/6/2003 15:24

<sup>27</sup> LOVERRE 88 reports a less stringent, indirect limit based on theoretical analysis of neutral to charged current ratios.

<sup>28</sup> ANGELINI 86 limit reaches  $13 \times 10^{-3}$  at  $\Delta(m^2) \approx 2 \text{ eV}^2$ .

- <sup>29</sup> BERNARDI 86B is a typical fit to the data, assuming mixing between two species. As the authors state, this result is in conflict with earlier upper bounds on this type of neutrino oscillations.
- <sup>30</sup>15ft bubble chamber at FNAL.

<sup>31</sup> ARMBRUSTER 02 is the final analysis of the KARMEN 2 data for 17.7 m distance from the ISIS stopped pion and muon neutrino source. It is a search for  $\overline{\nu}_e$ , detected by the inverser  $\beta$ -decay reaction on protons and <sup>12</sup>C. 15 candidate events are observed, and 15.8  $\pm$  0.5 background events are expected, hence no oscillation signal is detected. The results exclude large regions of the parameter area favored by the LSND experiment.

- <sup>32</sup> AGUILAR 01 is the final analyis of the LSND full data set. It is a search for  $\overline{\nu}_e$  30 m from LAMPF beam stop. Neutrinos originate mainly for  $\pi^+$  decay at rest.  $\overline{\nu}_e$  are detected through  $\overline{\nu}_e p \rightarrow e^+ n$  ( $20 < E_{e^+} < 60$  MeV) in delayed coincidence with  $np \rightarrow d\gamma$ . AUthors observe 87.9  $\pm$  22.4  $\pm$  6.0 total excess events. The observation is attributed to  $\overline{\nu}_{\mu} \rightarrow \overline{\nu}_e$  oscillations with the oscillation probability of 0.264  $\pm$  0.067  $\pm$  0.045%, consistent with the previously published result. Taking into account all constraints, the most favored allowed region of oscillation parameters is a band of  $\Delta(m^2)$  from 0.2–2.0 eV<sup>2</sup>. Supersedes ATHANASSOPOULOS 95, ATHANASSOPOULOS 96, and ATHANASSOPOULOS 98.
- <sup>33</sup> ATHANASSOPOULOS 96 is a search for  $\overline{\nu}_e$  30 m from LAMPF beam stop. Neutrinos originate mainly from  $\pi^+$  decay at rest.  $\overline{\nu}_e$  could come from either  $\overline{\nu}_\mu \rightarrow \overline{\nu}_e$  or  $\nu_e \rightarrow \overline{\nu}_e$ ; our entry assumes the first interpretation. They are detected through  $\overline{\nu}_e p \rightarrow e^+ n$  (20 MeV  $\langle E_{e^+} \rangle$  40 MeV) in delayed coincidence with  $np \rightarrow d\gamma$ . Authors observe 51 ± 20 ± 8 total excess events over an estimated background 12.5 ± 2.9. ATHANASSOPOULOS 96B is a shorter version of this paper.
- $^{34}$  ATHANASSOPOULOS 95 error corresponds to the  $1.6\sigma$  band in the plot. The expected background is 2.7  $\pm$  0.4 events. Corresponds to an oscillation probability of  $(0.34^{+0.20}_{-0.18}\pm0.07)\%$ . For a different interpretation, see HILL 95. Replaced by ATHANASSOPOULOS 96.

- <sup>35</sup> HILL 95 is a report by one member of the LSND Collaboration, reporting a different conclusion from the analysis of the data of this experiment (see ATHANASSOPOULOS 95). Contrary to the rest of the LSND Collaboration, Hill finds no evidence for the neutrino oscillation  $\overline{\nu}_{\mu} \rightarrow \overline{\nu}_{e}$  and obtains only upper limits.
- <sup>36</sup> FREEDMAN 93 is a search at LAMPF for  $\overline{\nu}_e$  generated from any of the three neutrino types  $\nu_{\mu}$ ,  $\overline{\nu}_{\mu}$ , and  $\nu_e$  which come from the beam stop. The  $\overline{\nu}_e$ 's would be detected by the reaction  $\overline{\nu}_e p \rightarrow e^+ n$ . FREEDMAN 93 replaces DURKIN 88.
- <sup>37</sup> In reaction  $\overline{\nu}_e p \rightarrow e^+ n$ .

<sup>49</sup> ESKUT 01 limit obtained following the statistical prescriptions in JUNK 99. The limit would have been 0.5 eV<sup>2</sup> if the prescriptions in FELDMAN 98 had been followed, as they were in ASTIER 01B.

 $^{50}$ ASTIER 01B limit is based on an oscillation probability  $< 1.63 \times 10^{-4}$ , whereas the quoted sensitivity was  $2.5 \times 10^{-4}$ . The limit was obtained following the statitical prescriptions of FELDMAN 98. See also the footnote to ESKUT 01.

<sup>51</sup>ALTEGOER 98B is the NOMAD 1995 data sample result, searching for events with  $\tau^- \rightarrow e^- \nu_\tau \overline{\nu}_e$ , hadron  $\nu_\tau$ , or  $\pi^- \pi^+ \pi^-$  decay modes using classical CL approach of FELDMAN 98.

<sup>52</sup> ESKUT 98 search for events with one  $\mu^-$  with indication of a kink from  $\tau^-$  decay in the nuclear emulsion. No candidates were found in a 31,423 event subsample.

<sup>53</sup> ESKUT 98B search for  $\tau^- \rightarrow \mu^- \nu_\tau \overline{\nu}_\mu$  or  $h^- \nu_\tau \overline{\nu}_\mu$ , where  $h^-$  is a negatively charged hadron. The  $\mu^-$  sample is somewhat larger than in ESKUT 98, which this result super-

 sedes. Bayesian limit.
 <sup>54</sup>LOVERRE 96 uses the charged-current to neutral-current ratio from the combined CHARM (ALLABY 86) and CDHS (ABRAMOWICZ 86) data from 1986.

 $^{74}$  EGUCHI 03 observe reactor neutrino disappearance at  $\sim 180\,\text{km}$  baseline to various Japanese nuclear power reactors. See the footnote in the following table for further details, and the paper for the inclusion/exclusion plot.

 $^{75}$  BOEHM 01 search for neutrino oscillations at 0.75 and 0.89 km distance from the Palo \_\_ Verde reactors.

- $^{76}$  BOEHM 00C search for neutrino oscillations at 0.75 and 0.89 km distance from the Palo  $_{-2}$  Verde reactors.
- <sup>77</sup> APOLLONIO 99, APOLLONIO 98 search for neutrino oscillations at 1.1 km fixed distance from Chooz reactors. They use  $\overline{\nu}_e p \rightarrow e^+ n$  in Gd-loaded scintillator target. APOLLONIO 99 supersedes APOLLONIO 98.
- $^{78}$  GREENWOOD 96 search for neutrino oscillations at 18 m and 24 m from the reactor at \_\_ Savannah River.
- <sup>79</sup> DECLAIS 94 result based on integral measurement of neutrons only. Result is ratio of measured cross section to that expected in standard V-A theory. Replaced by ACHKAR 95.
- <sup>80</sup> KWON 81 represents an analysis of a larger set of data from the same experiment as BOEHM 80.
- <sup>81</sup> REINES 80 involves comparison of neutral- and charged-current reactions  $\overline{\nu}_e d \rightarrow np\overline{\nu}_e$ and  $\overline{\nu}_e d \rightarrow nne^+$  respectively. Combined analysis of reactor  $\overline{\nu}_e$  experiments was performed by SILVERMAN 81.
- $^{82}$  The two REINES 80 values correspond to the calculated  $\overline{\nu}_e$  fluxes of AVIGNONE 80 and DAVIS 79 respectively.

 $^{83}$  EGUCHI 03 observe reactor neutrino disappearance at  $\sim 180\,{\rm km}$  baseline to various Japanese nuclear power reactors. This is the lower limit on the mass difference spread, unlike all other entries in this table. Observation is consistent with neutrino oscillations, with mass-mixing and mixing-angle parameters in the Large Mixing Angle Solution region of the solar neutrino problem.

<sup>84</sup> BOEHM 01, a continuation of BOEHM 00, is a disappearance search for neutrino oscillations at 0.75 and 0.89 km distance from the Palo Verde reactors. Result is less restrictive than APOLLONIO 99.

<sup>85</sup> BOEHM 00 is a disappearance search for neutrino oscillations at 0.75 and 0.89 km distance from Palo Verde reactors. The detection reaction is  $\overline{\nu}_e p \rightarrow e^+ n$  in a segmented Gd loaded scintillator target. Result is less restrictive than APOLLONIO 99.

<sup>86</sup> APOLLONIO 99 search for neutrino oscillations at 1.1 km fixed distance from Chooz reactors. They use  $\overline{\nu}_e p \rightarrow e^+ n$  in Gd-loaded scintillator target. APOLLONIO 99 supersedes APOLLONIO 98. This is the most sensitive search in terms of  $\Delta(m^2)$  for  $\overline{\nu}_e$  disappearance.

<sup>87</sup> ACHKAR 95 bound is for L=15, 40, and 95 m.

<sup>88</sup> VIDYAKIN 94 bound is for L=57.0 m, 57.6 m, and 231.4 m. Supersedes VIDYAKIN 90. <sup>89</sup> AFONIN 86 and AFONIN 87 also give limits on  $\sin^2(2\theta)$  for intermediate values of  $\Delta(m^2)$ . (See also KETOV 92). Supersedes AFONIN 87, AFONIN 86, AFONIN 85, AFONIN 83, and BELENKII 83.

 $^{90}$  VIDYAKIN 87 bound is for L=32.8 and 92.3 m distance from two reactors.  $^{91}$  This bound is from data for  $L{=}37.9$  m, 45.9 m, and 64.7 m.

 $^{92}$  EGUCHI 03 observe reactor neutrino disappearance at  $\sim 180 \, \rm km$  baseline to various Japanese nuclear power reactors. This is the lower limit on  $\sin^2 2\theta$ , unlike all other entries in this table. It is based on the observed rate only; consideration of the spectrum shape results in somewhat more restrictive limit. Observation is consistent with neutrino oscillations, with mass-mixing and mixing-angle parameters in the Large Mixing Angle Solution region of the solar neutrino problem.

<sup>94</sup> BOEHM 00 search for neutrino oscillations at 0.75 and 0.89 km distance from Palo Verde

<sup>95</sup> APOLLONIO 99 search for neutrino oscillations at 1.1 km fixed distance from Chooz reactors.

<sup>96</sup> GREENWOOD 96 search for neutrino oscillations at 18 m and 24 m from the reactor at Savannah River by observing  $\overline{\nu}_e p \rightarrow e^+ n$  in a Gd loaded scintillator target. Their region of sensitivity in  $\Delta(m^2)$  and  $\sin^2 2\theta$  is already excluded by ACHKAR 95.

 $^{97}$  ACHKAR 95 bound is from data for L=15, 40, and 95 m distance from the Bugey reactor.

- $^{98}$  The VYRODOV 95 bound is from data for L=15 m distance from the Bugey-5 reactor.
- <sup>99</sup> The VIDYAKIN 94 bound is from data for L=57.0 m, 57.6 m, and 231.4 m from three reactors in the Krasnoyarsk Reactor complex.
- <sup>100</sup> Several different methods of data analysis are used in AFONIN 88. We quote the most stringent limits. Different upper limits on  $\sin^2 2\theta$  apply at intermediate values of  $\Delta(m^2)$ . Supersedes AFONIN 87, AFONIN 85, and BELENKII 83.
- <sup>101</sup> VIDYAKIN 87 bound is for L = 32.8 and 92.3 m distance from two reactors.
- <sup>102</sup> This bound is from data for L=37.9 m, 45.9 m, and 64.7 m distance from Gosgen reactor. <sup>103</sup> ZACEK 85 gives two sets of bounds depending on what assumptions are used in the data analysis. The bounds in figure 3(a) of ZACEK 85 are progressively poorer for large  $\Delta(m^2)$  whereas those of figure 3(b) approach a constant. We list the latter. Both sets of bounds use combination of data from 37.9, 45.9, and 64.7m distance from reactor. ZACEK 85 states "Our experiment excludes this area (the oscillation parameter region allowed by the Bugey data, CAVAIGNAC 84) almost completely, thus disproving the indications of neutrino oscillations of CAVAIGNAC 84 with a high degree of confidence."
- <sup>104</sup> This bound comes from a combination of the VUILLEUMIER 82 data at distance 37.9m from Gosgen reactor and new data at 45.9m.

 $<sup>^{93}</sup>$  BOEHM 01 search for neutrino oscillations at 0.75 and 0.89 km distance from the Palo Verde reactors. Continuation of BOEHM 00.

#### (C) Atmospheric neutrino observations

Neutrinos and antineutrinos produced in the atmosphere induce  $\mu$ -like and e-like events in underground detectors. The ratio of the numbers of the two kinds of events is defined as  $\mu/e$ . It has the advantage that systematic effects, such as flux uncertainty, tend to cancel, for both experimental and theoretical values of the ratio. The "ratio of the ratios" of experimental to theoretical  $\mu/e$ ,  $R(\mu/e)$ , or that of experimental to theoretical  $\mu/$ total,  $R(\mu/$ total) with total =  $\mu+e$ , is reported below. If the actual value is not unity, the value obtained in a given experiment may depend on the experimental conditions.

$R(\mu/e) = $ (Measured Ratio	$\mu/e$ / (Expected	d Ra	atio $\mu/c$	e)

 $^{105}$  ALLISON 99 result is based on an exposure of 3.9 kton yr, 2.6 times the exposure reported in ALLISON 97, and replaces that result.

- $^{106}$  FUKUDA 98 result is based on an exposure of 25.5 kton yr. The analyzed data sample consists of fully-contained *e*-like events with 0.1 GeV/*c*<*p*<sub>e</sub> and *µ*-like events with 0.2 GeV/*c*<*p*<sub>µ</sub>, both having a visible energy < 1.33 GeV. These criteria match the definition used by FUKUDA 94.
- <sup>107</sup> FUKUDA 98E result is based on an exposure of 25.5 kton yr. The analyzed data sample consists of fully-contained single-ring events with visible energy > 1.33 GeV and partially contained events. All partially contained events are classified as  $\mu$ -like.

<sup>108</sup> FUKUDA 96B studied neutron background in the atmospheric neutrino sample observed in the Kamiokande detector. No evidence for the background contamination was found.

- <sup>109</sup> DAUM 95 results are based on an exposure of 2.0 kton yr which includes the data used by BERGER 90B. This ratio is for the contained and semicontained events. DAUM 95 also report  $R(\mu/e) = 0.99 \pm 0.13 \pm 0.08$  for the total neutrino induced data sample which includes upward going stopping muons and horizontal muons in addition to the contained and semicontained events.
- <sup>110</sup> FUKUDA 94 result is based on an exposure of 7.7 kton yr and updates the HIRATA 92 result. The analyzed data sample consists of fully-contained *e*-like events with 0.1 <  $p_e < 1.33 \text{ GeV}/c$  and fully-contained  $\mu$ -like events with 0.2 <  $p_{\mu} < 1.5 \text{ GeV}/c$ .
- <sup>111</sup> FUKUDA 94 analyzed the data sample consisting of fully contained events with visible energy > 1.33 GeV and partially contained  $\mu$ -like events.
- <sup>112</sup> BECKER-SZENDY 92B reports the fraction of nonshowering events (mostly muons from atomospheric neutrinos) as 0.36  $\pm$  0.02  $\pm$  0.02, as compared with expected fraction 0.51  $\pm$  0.01  $\pm$  0.05. After cutting the energy range to the Kamiokande limits, BEIER 92 finds  $R(\mu/e)$  very close to the Kamiokande value.

$R( u_{\mu}) = (Measur)$	red Flux of $\nu_{\mu}$ ) /	(Exp	pected	Flux of $ u_{\mu}$ )

- $^{113}\,\rm AMBROSIO$  01 result is based on the upward through-going muon tracks with  $E_{\mu}>1$  GeV. The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration, is 6.17 years. The first error is the statistical error, the second is the systematic error, dominated by the theoretical error in the predicted flux.
- <sup>114</sup> AMBROSIO 00 result is based on the upgoing partially contained event sample. It came from 4.1 live years of data taking with the full detector, from April 1994 to February 1999. The average energy of atmospheric muon neutrinos corresponding to this sample is 4 GeV. The first error is statistical, the second is the systematic error, dominated by the 25% theoretical error in the rate (20% in the flux and 15% in the cross section, added in quadrature). Within statistics, the observed deficit is uniform over the zenith angle.
- <sup>115</sup> AMBROSIO 00 result is based on the combined samples of downgoing partially contained events and upgoing stopping events. These two subsamples could not be distinguished due to the lack of timing information. The result came from 4.1 live years of data taking with the full detector, from April 1994 to February 1999. The average energy of atmospheric muon neutrinos corresponding to this sample is 4 GeV. The first error is statistical, the second is the systematic error, dominated by the 25% theoretical error in the rate (20% in the flux and 15% in the cross section, added in quadrature). Within statistics, the observed deficit is uniform over the zenith angle.
- <sup>116</sup> AMBROSIO 98 result is for all nadir angles and updates AHLEN 95 result. The lower cutoff on the muon energy is 1 GeV. In addition to the statistical and systematic errors, there is a Monte Carlo flux error (theoretical error) of  $\pm 0.13$ . With a neutrino oscillation hypothesis, the fit either to the flux or zenith distribution independently yields  $\sin^2 2\theta = 1.0$  and  $\Delta(m^2) \sim$  a few times  $10^{-3} \text{ eV}^2$ . However, the fit to the observed zenith distribution gives a maximum probability for  $\chi^2$  of only 5% for the best oscillation hypothesis.
- <sup>117</sup> CASPER 91 correlates showering/nonshowering signature of single-ring events with parent atmospheric-neutrino flavor. They find nonshowering ( $\approx \nu_{\mu}$  induced) fraction is  $0.41 \pm 0.03 \pm 0.02$ , as compared with expected  $0.51 \pm 0.05$  (syst).
- <sup>118</sup> AGLIETTA 89 finds no evidence for any anomaly in the neutrino flux. They define  $\rho = (\text{measured number of } \nu_e's)/(\text{measured number of } \nu_\mu's)$ . They report  $\rho(\text{measured}) = \rho(\text{expected}) = 0.96 \substack{+0.32 \\ -0.28}$ .
- <sup>119</sup> From this data BOLIEV 81 obtain the limit  $\Delta(m^2) \leq 6 \times 10^{-3} \text{ eV}^2$  for maximal mixing,  $\nu_{\mu} \not\rightarrow \nu_{\mu}$  type oscillation.

- $^{132}$ AMBROSIO 01 result is based on the angular distribution of upward through-going muon tracks with  $E_{\mu} > 1$  GeV. The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration, is 6.17 years. The best fit is obtained outside the physical region. The method of FELDMAN 98 is used to obtain the limits.
- $^{133}$ AMBROSIO 01 result is based on the angular distribution and normalization of upward through-going muon tracks with  $E_{\mu}$  > 1 GeV. The best fit is obtained outside the physical region. The method of FÉLDMAN 98 is used to obtain the limits. See the previous footnote.
- $^{134}$  AMBROSIO 00 obtained this result by using the upgoing partially contained event sample and the combined samples of downgoing partially contained events and upgoing stopping events. These data came from 4.1 live years of data taking with the full detector, from April 1994 to February 1999. The average energy of atmospheric muon neutrinos corresponding to these samples is 4 GeV. The maximum of the  $\chi^2$  probability (97%) occurs at maximal mixing and  $\Delta(m^2) = (1 \sim 20) \times 10^{-3} \text{ eV}^2$ .

- <sup>135</sup> FUKUDA 99C obtained this result from a total of 537 live days of upward through-going muon data in Super-Kamiokande between April 1996 to January 1998. With a threshold of  $E_{\mu} > 1.6$  GeV, the observed flux of upward through-going muons is  $(1.74 \pm 0.07 \pm 0.02) \times 10^{-13}$  cm<sup>-2</sup> s<sup>-1</sup> sr<sup>-1</sup>. The zenith-angle dependence of the flux does not agree with no-oscillation predictions. For the  $\nu_{\mu} \rightarrow \nu_{\tau}$  hypothesis, FUKUDA 99C obtained the best fit at sin<sup>2</sup>2 $\theta$ =0.95 and  $\Delta(m^2)$ =5.9 × 10<sup>-3</sup> eV<sup>2</sup>. FUKUDA 99C also reports 68% and 99% confidence-level allowed regions for the same hypothesis.
- <sup>136</sup> FUKUDA 99D obtained this result from a simultaneous fitting to zenith angle distributions of upward-stopping and through-going muons. The flux of upward-stopping muons of minimum energy of 1.6 GeV measured between April 1996 and January 1998 is  $(0.39 \pm 0.04 \pm 0.02) \times 10^{-13} \text{ cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$ . This is compared to the expected flux of  $(0.73 \pm 0.16 \text{ (theoretical error)}) \times 10^{-13} \text{ cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$ . The flux of upward through-going muons is taken from FUKUDA 99C. For the  $\nu_{\mu} \rightarrow \nu_{\tau}$  hypothesis, FUKUDA 99D obtained the best fit in the physical region at  $\sin^2 2\theta = 1.0$  and  $\Delta(m^2) = 3.9 \times 10^{-3} \text{ eV}^2$ . FUKUDA 99D further reports the result of the oscillation analysis using the zenith-angle dependence of upward-stopping/through-going flux ratio. The best fit in the physical region is obtained at  $\sin^2 2\theta = 1.0$  and  $\Delta(m^2) = 3.1 \times 10^{-3} \text{ eV}^2$ .
- <sup>137</sup> AMBROSIO 98 result is only 17% probable at maximum because of relatively low flux for  $\cos\theta < -0.8$ .
- <sup>138</sup> FUKUDA 98C obtained this result by an analysis of 33.0 kton yr atmospheric-neutrino data which include the 25.5 kton yr data used by FUKUDA 98 (sub-GeV) and FUKUDA 98E (multi-GeV). Inside the physical region, the best fit was obtained at  $\sin^2 2\theta = 1.0$  and  $\Delta(m^2) = 2.2 \times 10^{-3} \text{ eV}^2$ . In addition, FUKUDA 98C gave the 99% confidence interval,  $\sin^2 2\theta > 0.73$  and  $3 \times 10^{-4} < \Delta(m^2) < 8.5 \times 10^{-3} \text{ eV}^2$ . FUKUDA 98C also tested the  $\nu_{\mu} \rightarrow \nu_e$  hypothesis, and concluded that it is not favored.
- <sup>139</sup> HATAKEYAMA 98 obtained this result from a total of 2456 live days of upwardgoing muon data in Kamiokande between December 1985 and May 1995. With a threshold of  $E_{\mu} > 1.6$  GeV, the observed flux of upward through-going muon is  $(1.94 \pm 0.10^{+0.07}_{-0.06}) \times 10^{-13}$  cm<sup>-2</sup>s<sup>-1</sup>sr<sup>-1</sup>. This is compared to the expected flux of  $(2.46 \pm 0.54$  (theoretical error))  $\times 10^{-13}$  cm<sup>-2</sup>s<sup>-1</sup>sr<sup>-1</sup>. For the  $\nu_{\mu} \rightarrow$  $\nu_{\tau}$  hypothesis, the best fit inside the physical region was obtained at sin<sup>2</sup>2 $\theta$ =1.0 and  $\Delta(m^2)$ =3.2  $\times 10^{-3}$  eV<sup>2</sup>.
- <sup>140</sup> HATAKEYAMA 98 obtained this result from a combined analysis of Kamiokande's contained events (FUKUDA 94) and upward-going muon events. The best fit was obtained at  $\sin^2 2\theta = 0.95$  and  $\Delta(m^2) = 1.3 \times 10^{-2} \text{ eV}^2$ .
- $^{141}$  CLARK 97 obtained this result by an analysis of fully contained and partially contained events in the IMB water-Cerenkov detector with visible energy > 0.95 GeV.
- <sup>142</sup> FUKUDA 94 obtained this result by a combined analysis of sub-and multi-GeV atmospheric neutrino events in Kamiokande.
- <sup>143</sup>BECKER-SZENDY 92 uses upward-going muons to search for atmospheric  $\nu_{\mu}$  oscillations. The fraction of muons which stop in the detector is used to search for deviations in the expected spectrum. No evidence for oscillations is found.
- <sup>144</sup> BERGER 90B uses the Frejus detector to search for oscillations of atmospheric neutrinos. Bounds are for both neutrino and antinuetrino oscillations.

- $^{145}$  AMBROSIO 01 result is based on the angular distribution of upward through-going muon tracks with  $E_{\mu} > 1~{\rm GeV}$ . The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration, is 6.17 years. The best fit is obtained outside the physical region. The method of FELDMAN 98 is used to obtain the limits.
- $^{146}\,\rm AMBROSIO$  01 result is based on the angular distribution and normalization of upward through-going muon tracks with  $E_{\mu} > 1$  GeV. The best fit is obtained outside the physical region. The method of FELDMAN 98 is used to obtain the limits. See the previous footnote.
- <sup>147</sup> AMBROSIO 00 obtained this result by using the upgoing partially contained event sample and the combined samples of downgoing partially contained events and upgoing stopping events. These data came from 4.1 live years of data taking with the full detector, from April 1994 to February 1999. The average energy of atmospheric muon neutrinos corresponding to these samples is 4 GeV. The maximum of the  $\chi^2$  probability (97%) occurs at maximal mixing and  $\Delta(m^2) = (1 \sim 20) \times 10^{-3} \text{ eV}^2$ .
- <sup>148</sup> FUKUDA 99C obtained this result from a total of 537 live days of upward through-going muon data in Super-Kamiokande between April 1996 to January 1998. With a threshold of  $E_{\mu} > 1.6$  GeV, the observed flux of upward through-going muon is  $(1.74 \pm 0.07 \pm 0.02) \times 10^{-13}$  cm<sup>-2</sup> s<sup>-1</sup> sr<sup>-1</sup>. The zenith-angle dependence of the flux does not agree with no-oscillation predictions. For the  $\nu_{\mu} \rightarrow \nu_{\tau}$  hypothesis, FUKUDA 99C obtained the best fit at sin<sup>2</sup>2 $\theta$ =0.95 and  $\Delta(m^2)$ =5.9 × 10<sup>-3</sup> eV<sup>2</sup>. FUKUDA 99C also reports 68% and 99% confidence-level allowed regions for the same hypothesis.
- <sup>149</sup> FUKUDA 99D obtained this result from a simultaneous fitting to zenith angle distributions of upward-stopping and through-going muons. The flux of upward-stopping muons of minimum energy of 1.6 GeV measured between April 1996 and January 1998 is  $(0.39 \pm 0.04 \pm 0.02) \times 10^{-13} \text{ cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$ . This is compared to the expected flux of  $(0.73 \pm 0.16 \text{ (theoretical error)}) \times 10^{-13} \text{ cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$ . The flux of upward throughgoing muons is taken from FUKUDA 99C. For the  $\nu_{\mu} \rightarrow \nu_{\tau}$  hypothesis, FUKUDA 99D obtained the best fit in the physical region at  $\sin^2 2\theta = 1.0$  and  $\Delta(m^2) = 3.9 \times 10^{-3} \text{ eV}^2$ . FUKUDA 99D further reports the result of the oscillation analysis using the zenith-angle dependence of upward-stopping/through-going flux ratio. The best fit in the physical region is obtained at  $\sin^2 2\theta = 1.0$  and  $\Delta(m^2) = 3.1 \times 10^{-3} \text{ eV}^2$ .
- $^{150}\,{\rm AMBROSIO}$  98 result is only 17% probable at maximum because of relatively low flux for  $\cos\!\theta < -0.8.$

- <sup>151</sup> FUKUDA 98C obtained this result by an analysis of 33.0 kton yr atmospheric-neutrino data which include the 25.5 kton yr data used by FUKUDA 98 (sub-GeV) and FUKUDA 98E (multi-GeV). Inside the physical region, the best fit was obtained at  $\sin^2 2\theta = 1.0$  and  $\Delta(m^2) = 2.2 \times 10^{-3} \text{ eV}^2$ . In addition, FUKUDA 98C gave the 99% confidence interval,  $\sin^2 2\theta > 0.73$  and  $3 \times 10^{-4} < \Delta(m^2) < 8.5 \times 10^{-3} \text{ eV}^2$ . FUKUDA 98C also tested the  $\nu_{\mu} \rightarrow \nu_e$  hypothesis, and concluded that it is not favored.
- <sup>152</sup> HATAKEYAMA 98 obtained this result from a total of 2456 live days of upwardgoing muon data in Kamiokande between December 1985 and May 1995. With a threshold of  $E_{\mu} > 1.6$  GeV, the observed flux of upward through-going muon is  $(1.94 \pm 0.10 \substack{+0.07 \\ -0.06}) \times 10^{-13}$  cm<sup>-2</sup> s<sup>-1</sup> sr<sup>-1</sup>. This is compared to the expected flux of (2.46 ± 0.54 (theoretical error))  $\times 10^{-13}$  cm<sup>-2</sup> s<sup>-1</sup> sr<sup>-1</sup>. For the  $\nu_{\mu} \rightarrow \nu_{\tau}$  hypothesis, the best fit inside the physical region was obtained at sin<sup>2</sup>2 $\theta$ =1.0 and

 $\Delta(m^2) = 3.2 \times 10^{-3} \text{ eV}^2$ .

- <sup>153</sup> HATAKEYAMA 98 obtained this result from a combined analysis of Kamiokande's contained events (FUKUDA 94) and upward-going muon events. The best fit was obtained at  $\sin^2 2\theta = 0.95$  and  $\Delta(m^2) = 1.3 \times 10^{-2} \text{ eV}^2$ .
- <sup>154</sup> CLARK 97 obtained this result by an analysis of fully contained and partially contained events in the IMB water-Cerenkov detector with visible energy > 0.95 GeV.
- <sup>155</sup> FUKUDA 94 obtained this result by a combined analysis of sub-and multi-GeV atmospheric neutrino events in Kamiokande.

156 BERGER 90B uses the Frejus detector to search for oscillations of atmospheric neutrinos. Bounds are for both neutrino and antinuetrino oscillations.

## $\Delta(m^2)$ for sin<sup>2</sup>(2 $\theta$ ) = 1 ( $\nu_{\mu} \rightarrow \nu_s$ )

$\nu_{s}$ means $\nu_{\tau}$ or any sterile (noninteracting) $\nu$ .	
--	--

	<sup>158</sup> AMBROSIO	01	MCRO	matter effects
	<sup>159</sup> FUKUDA	00	SKAM	neutral currents $+$ mat-
150				ter effects

- <sup>158</sup> AMBROSIO 01 tested the pure 2-flavor  $\nu_{\mu} \rightarrow \nu_{s}$  hypothesis using matter effects which change the shape of the zenith-angle distribution of upward through-going muons. With maximum mixing and  $\Delta(m^2)$  around 0.0024 eV<sup>2</sup>, the  $\nu_{\mu} \rightarrow \nu_{s}$  oscillation is disfavored with 99% confidence level with respect to the  $\nu_{\mu} \rightarrow \nu_{\tau}$  hypothesis.
- <sup>159</sup> FUKUDA 00 tested the pure 2-flavor  $\nu_{\mu} \rightarrow \nu_{s}$  hypothesis using three complementary atmospheric-neutrino data samples. With this hypothesis, zenith-angle distributions are expected to show characteristic behavior due to neutral currents and matter effects. In the  $\Delta(m^2)$  and  $\sin^2 2\theta$  region preferred by the Super-Kamiokande data, the  $\nu_{\mu} \rightarrow \nu_{s}$  hypothesis is rejected at the 99% confidence level, while the  $\nu_{\mu} \rightarrow \nu_{\tau}$  hypothesis consistently fits all of the data sample.

<sup>160</sup> ABDURASHITOV 02 report a combined analysis of 92 runs of the SAGE solar-neutrino experiment during the period January 1990 through December 2001, and updates the ABDURASHITOV 99B result. A total of 406.4 <sup>71</sup>Ge events were observed. No evidence was found for temporal variations of the neutrino capture rate over the entire observation period.

- <sup>161</sup> ALTMANN 00 report the first result from the GNO solar-neutrino experiment (GNO I), which is the successor project of GALLEX. Experimental technique of GNO is essentially the same as that of GALLEX. The run data cover the period 20 May 1998 through 12 January 2000.
- <sup>162</sup> Combined result of GALLEX I+II+III+IV (HAMPEL 99) and GNO I. The indicated errors include systematic errors.
- $^{163}$  HAMPEL 99 report the combined result for GALLEX I+II+III+IV (65 runs in total), which update the HAMPEL 96 result. The GALLEX IV result (12 runs) is 118.4  $\pm$  17.8  $\pm$  6.6 SNU. (HAMPEL 99 discuss the consistency of partial results with the mean.) The GALLEX experimental program has been completed with these runs. The total run data cover the period 14 May 1991 through 23 January 1997. A total of 300  $^{71}$ Ge events were observed.

<sup>164</sup> CLEVELAND 98 is a detailed report of the <sup>37</sup>Cl experiment at the Homestake Mine. The average solar neutrino-induced <sup>37</sup>Ar production rate from 108 runs between 1970 and 1994 updates the DAVIS 89 result.

## φ<sub>ES</sub> (<sup>8</sup>B)

 $^{8}\text{B}$  solar-neutrino flux measured via  $\nu\,e$  elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to  $\nu_{\mu}$ ,  $\nu_{\tau}$  due to the cross-section difference,  $\sigma(\nu_{\,\mu,\tau}\,e)\sim 0.16\sigma(\nu_{e}\,e)$ . If the  $^{8}\text{B}$  solar-neutrino flux involves nonelectron flavor active neutrinos, their contribution to the flux is  $\sim 0.16$  times of  $\nu_{e}$ .

<sup>165</sup>AHMAD 02 reports the <sup>8</sup>B solar-neutrino flux measured via  $\nu e$  elastic scattering above the kinetic energy threshold of 5 MeV. The data correspond to 306.4 live days with SNO between November 2, 1999 and May 28, 2001, and updates AHMAD 01 results.

<sup>166</sup> FUKUDA 02 results are for 1496 live days with Super-Kamiokande between May 31, 1996 and July 15, 2002, and replace FUKUDA 01 results. The analysis threshold is 5 MeV except for the first 280 live days (6.5 MeV).

<sup>167</sup>AHMAD 01 reports the <sup>8</sup>B solar-neutrino flux measured via  $\nu e$  elastic scattering above the kinetic energy threshold of 6.75 MeV. The data correspond to 241 live days with SNO between November 2, 1999 and January 15, 2001.

 $^{168}$  FUKUDA 96 results are for a total of 2079 live days with Kamiokande II and III from January 1987 through February 1995, covering the entire solar cycle 22, with threshold  $E_{
m 
ho} > 9.3$  MeV (first 449 days), > 7.5 MeV (middle 794 days), and > 7.0 MeV (last 836 days). These results update the HIRATA 90 result for the average <sup>8</sup>B solar-neutrino flux and HIRATA 91 result for the day-night variation in the <sup>8</sup>B solar-neutrino flux. The total data sample was also analyzed for short-term variations: within experimental errors, no strong correlation of the solar-neutrino flux with the sunspot numbers was found.
