¹ KALBFLEISCH 04 reports searches for stopped magnetic monopoles in Be, Al, and Pb samples obtained from discarded material from the upgrading of DØ and CDF. A large-aperture warm-bore cryogenic detector was used. The approach was an extension of the methods of KALBFLEISCH 00. Results are model dependent.

² KALBFLEISCH 00 used an induction method to search for stopped monopoles in pieces of the DØ (FNAL) beryllium beam pipe and in extensions to the drift chamber aluminum support cylinder. Results are model dependent.

³ KALBFLEISCH 00 result is for aluminum.

⁴ KALBFLEISCH 00 result is for beryllium.

⁵ HE 97 used a lead target and barium phosphate glass detectors. Cross-section limits are well below those predicted via the Drell-Yan mechanism.

⁶ Multiphoton events.

⁷ Cherenkov radiation polarization.

⁸ Re-examines CERN neutrino experiments.

Monopole Production — Other Accelerator Searches

> 510			88-94	e^+e^-	¹⁰ ACCIARRI	95C L3

⁹ ABBOTT 98K search for heavy pointlike Dirac monopoles via central production of a pair of photons with high transverse energies.

¹⁰ ACCIARRI 95C finds a limit $B(Z \rightarrow \gamma\gamma\gamma) < 0.8 \times 10^{-5}$ (which is possible via a monopole loop) at 95% CL and sets the mass limit via a cross section model.

Monopole Flux — Cosmic Ray Searches

“Caty” in the charge column indicates a search for monopole-catalyzed nucleon decay.

The absence of an entry usually means a track-etch experiment.

- <5.E-15 <15 <3 concentrator 0 CARITHERS 66 ELEC
 <2.E-11 <1-3 concentrator 0 MALKUS 51 EMUL
- ¹¹ AMBROSIO 02B direct search final result for $m \geq 10^{17}$ GeV, based upon 4.2 to 9.5 years of running, depending upon the subsystem. Limit with CR39 track-etch detector extends the limit from $\beta=4 \times 10^{-5}$ ($3.1 \times 10^{-16} \text{ cm}^{-2} \text{ sr}^{-1} \text{ s}^{-1}$) to $\beta=1 \times 10^{-4}$ ($2.1 \times 10^{-16} \text{ cm}^{-2} \text{ sr}^{-1} \text{ s}^{-1}$). Limit curve in paper is piecewise continuous due to different detection techniques for different β ranges.
- ¹² AMBROSIO 02C limit for catalysis of nucleon decay with catalysis cross section of ≈ 1 mb. The flux limit increases by ~ 3 at the higher β limit, and increases to $1 \times 10^{-14} \text{ cm}^{-2} \text{ sr}^{-1} \text{ s}^{-1}$ if the catalysis cross section is 0.01 mb. Based upon 71193 hr of data with the streamer detector, with an acceptance of $4250 \text{ m}^2 \text{ sr}$.
- ¹³ AMBROSIO 02D result for "more than two years of data." Ionization search using several subsystems. Limit curve as a function of β not given. Included in AMBROSIO 02B.
- ¹⁴ AMBROSIO 97 global MACRO 90%CL is 0.78×10^{-15} at $\beta=1.1 \times 10^{-4}$, goes through a minimum at 0.61×10^{-15} near $\beta=(1.1-2.7) \times 10^{-3}$, then rises to 0.84×10^{-15} at $\beta=0.1$. The global limit in this region is below the Parker bound at 10^{-15} . Less stringent limits are established for $4 \times 10^{-5} < \beta < 1 \times 10^{-4}$. Limits set by various triggers and different subdetectors are given in the paper. All limits assume a catalysis cross section smaller than a few mb.
- ¹⁵ AHLEN 94 limit for dyons extends down to $\beta=0.9\text{E}-4$ and a limit of $1.3\text{E}-14$ extends to $\beta = 0.8\text{E}-4$. Also see comment by PRICE 94 and reply of BARISH 94. One loophole in the AHLEN 94 result is that in the case of monopoles catalyzing nucleon decay, relativistic particles could veto the events. See AMBROSIO 97 for additional results.
- ¹⁶ Catalysis of nucleon decay; sensitive to assumed catalysis cross section.
- ¹⁷ ORITO 91 limits are functions of velocity. Lowest limits are given here.
- ¹⁸ Used DKMPR mechanism and Penning effect.
- ¹⁹ Assumes monopole attaches fermion nucleus.
- ²⁰ Limit from combining data of CAPLIN 86, BERMON 85, INCANDELA 84, and CABRERA 83. For a discussion of controversy about CAPLIN 86 observed event, see GUY 87. Also see SCHOUTEN 87.
- ²¹ Based on lack of high- energy solar neutrinos from catalysis in the sun.
- ²² Anomalous long-range α (^4He) tracks.
- ²³ CABRERA 82 candidate event has single Dirac charge within $\pm 5\%$.
- ²⁴ ALVAREZ 75, FLEISCHER 75, and FRIEDLANDER 75 explain as fragmenting nucleus. EBERHARD 75 and ROSS 76 discuss conflict with other experiments. HAGSTROM 77 reinterprets as antinucleus. PRICE 78 reassesses.

²⁵ Catalysis of nucleon decay.

²⁶ ADAMS 93 limit based on "survival and growth of a small galactic seed field" is $10^{-16} (m/10^{17} \text{ GeV}) \text{ cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$. Above 10^{17} GeV , limit $10^{-16} (10^{17} \text{ GeV}/m) \text{ cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$ (from requirement that monopole density does not overclose the universe) is more stringent.

²⁷ Re-evaluates PARKER 70 limit for GUT monopoles.
