Nearly all branching fractions of the Λ_c^+ are measured relative to the $pK^-\pi^+$ mode, but there are no model-independent measurements of this branching fraction. We explain how we arrive at our value of $B(\Lambda_c^+ \rightarrow pK^-\pi^+)$ in a Note at the beginning of the branching-ratio measurements in the Listings. When this branching fraction is eventually well determined, all the other branching fractions will slide up or down proportionally as the true value differs from the value we use here.

$\Lambda_c(2595)^+$

$$I(J^P) = 0(\frac{1}{2}^-)$$

The spin-parity follows from the fact that $\Sigma_c(2455)\pi$ decays, with little available phase space, are dominant. This assumes that $J^P = 1/2^+$ for the $\Sigma_c(2455)$.

$$\begin{aligned} \text{Mass } m &= 2592.25 \pm 0.28 \text{ MeV} \\ m - m_{\Lambda_c^+} &= 305.79 \pm 0.24 \text{ MeV} \\ \text{Full width } \Gamma &= 2.6 \pm 0.6 \text{ MeV} \end{aligned}$$

$\Lambda_c^+\pi\pi$ and its submode $\Sigma_c(2455)\pi$ — the latter just barely — are the only strong decays allowed to an excited Λ_c^+ having this mass; and the submode seems to dominate.

NOTES

- [a] See the note on “ Λ_c^+ Branching Fractions” in the Λ_c^+ Particle Listings.
- [b] This branching fraction includes all the decay modes of the final-state resonance.
- [c] An ℓ indicates an e or a μ mode, not a sum over these modes.
- [d] The value is for the sum of the charge states or particle/antiparticle states indicated.
- [e] Assuming isospin conservation, so that the other third is $\Lambda_c^+ \pi^0 \pi^0$.
- [f] A test that the isospin is indeed 0, so that the particle is indeed a Λ_c^+ .
- [g] No absolute branching fractions have been measured. The value here is the branching *ratio* relative to $\Xi^- 2\pi^+$.
