[7] KHACHATRYAN 15BC use the cross section measurement of the final state $pp \to ZZ \to 2\ell2\nu$, (ℓ being an electron or a muon) at 7 and 8 TeV to put limits on these triple gauge couplings. Effective mass of the charged lepton pair is required to be in the range 83.5–98.5 GeV and the dilepton $p_T > 45$ GeV. The reduced missing E_T is required to be > 65 GeV, which takes into account the fake missing E_T due to detector effects. The numbers of e^+e^- and $\mu^+\mu^-$ events selected are 35 and 40 at 7 TeV and 176 and 271 at 8 TeV respectively. The production cross sections so obtained are in agreement with SM predictions. The following 95% C.L. limits are set: $-0.0028 < f_4^Z < 0.0032$, $-0.0037 < f_4^\gamma < 0.0033$, $-0.0029 < f_5^Z < 0.0031$, $-0.0033 < f_5^\gamma < 0.0037$. Combining with previous results (KHACHATRYAN 15B and CHATRCHYAN 13B) which include 7 TeV and 8 TeV data on the final states $pp \to ZZ \to 2\ell2\ell'$ where ℓ and ℓ' are an electron or a muon, the best limits are $-0.0022 < f_4^Z < 0.0026$, $-0.0029 < f_4^\gamma < 0.0026$, $-0.0023 < f_5^Z < 0.0023$, $-0.0026 < f_5^\gamma < 0.0027$.

[8] AAD 13Z study ZZ production in pp collisions at $\sqrt{s} = 7$ TeV. In the $ZZ \to \ell^+\ell^-\ell'^+\ell'^-$ final state they observe a total of 66 events with an expected background of 0.9 ± 1.3. In the $ZZ \to \ell^+\ell^-\nu\nu$ final state they observe a total of 87 events with an expected background of 46.9 ± 5.2. The limits on anomalous TGCs are determined using the observed and expected numbers of these ZZ events binned in p_T^Z. The 95% C.L. are as follows: for form factor scale $\Lambda = \infty$, $-0.015 < f_4^\gamma < 0.015$, $-0.013 < f_4^Z < 0.013$, $-0.016 < f_5^\gamma < 0.015$, $-0.013 < f_5^Z < 0.013$; for form factor scale $\Lambda = 3$ TeV, $-0.022 < f_4^\gamma < 0.023$, $-0.019 < f_4^Z < 0.019$, $-0.023 < f_5^\gamma < 0.023$, $-0.020 < f_5^Z < 0.019$.

[9] CHATRCHYAN 13B study ZZ production in pp collisions and select 54 ZZ candidates in the Z decay channel with electrons or muons with an expected background of 1.4 ± 0.5 events. The resulting 95% C.L. ranges are: $-0.013 < f_4^\gamma < 0.015$, $-0.011 < f_4^Z < 0.012$, $-0.014 < f_5^\gamma < 0.014$, $-0.012 < f_5^Z < 0.012$.

[10] Using data collected in the center of mass energy range 192–209 GeV, SCHAEL 09 select 318 $e^+e^- \to ZZ$ events with 319.4 expected from the standard model. Using this data they derive the following 95% CL limits: $-0.321 < f_4^\gamma < 0.318$, $-0.534 < f_4^Z < 0.534$, $-0.724 < f_5^\gamma < 0.733$, $-1.194 < f_5^Z < 1.190$.

[11] ABAZOV 08K search for ZZ and $Z\gamma^*$ events with 1 fb^{-1} $p\overline{p}$ data at $\sqrt{s} = 1.96$ TeV in $(ee)(ee)$, $(\mu\mu)(\mu\mu)$, $(ee)(\mu\mu)$ final states requiring the lepton pair masses to be > 30 GeV. They observe 1 event, which is consistent with an expected signal of 1.71 ± 0.15 events and a background of 0.13 ± 0.03 events. From this they derive the following limits, for a form factor (Λ) value of 1.2 TeV: $-0.28 < f_{40}^Z < 0.28$, $-0.31 < f_{50}^Z < 0.29$, $-0.26 < f_{40}^\gamma < 0.26$, $-0.30 < f_{50}^\gamma < 0.28$.

[12] Using data collected at $\sqrt{s} = 183$–208 GeV, ABDALLAH 07C select 171 $e^+e^- \to ZZ$ events with $Z \to q\overline{q}$ or lepton pair (except an explicit τ pair), and 74 $e^+e^- \to Z\gamma^*$ events with a $q\overline{q}\mu^+\mu^-$ or $q\overline{q}e^+e^-$ signature, to derive 95% CL limits on f_i^V. Each limit is derived with other parameters set to zero. They report: $-0.40 < f_4^Z < 0.42$, $-0.38 < f_5^Z < 0.62$, $-0.23 < f_4^\gamma < 0.25$, $-0.52 < f_5^\gamma < 0.48$.

[13] ABBIENDI 04C study ZZ production in e^+e^- collisions in the C.M. energy range 190–209 GeV. They select 340 events with an expected background of 180 events. Including the ABBIENDI 00N data at 183 and 189 GeV (118 events with an expected background of 65 events) they report the following 95% CL limits: $-0.45 < f_4^Z < 0.58$, $-0.94 < f_5^Z < 0.25$, $-0.32 < f_4^\gamma < 0.33$, and $-0.71 < f_5^\gamma < 0.59$.

[14] ACHARD 03D study Z-boson pair production in e^+e^- collisions in the C.M. energy range 200–209 GeV. They select 549 events with an expected background of 432 events. Including the ACCIARRI 99G and ACCIARRI 99O data (183 and 189 GeV respectively, 286 events with an expected background of 241 events) and the 192–202 GeV ACCIARRI 01I results (656 events, expected background of 512 events), they report the following 95% CL limits: $-0.48 \le f_4^Z \le 0.46$, $-0.36 \le f_5^Z \le 1.03$, $-0.28 \le f_4^\gamma \le 0.28$, and $-0.40 \le f_5^\gamma \le 0.47$.

ANOMALOUS W/Z QUARTIC COUPLINGS

Revised March 2024 by M.W. Grünewald (U. College Dublin) and A. Gurtu (CERN; TIFR Mumbay).

Quartic couplings, $WWZZ$, $WWZ\gamma$, $WW\gamma\gamma$, and $ZZ\gamma\gamma$, were studied at LEP and Tevatron at energies at which the Standard Model predicts negligible contributions to multiboson production. Thus, to parametrize limits on these couplings, an effective theory approach is adopted which supplements the

Standard Model Lagrangian with higher dimensional operators which include quartic couplings. The LEP collaborations chose the lowest dimensional representation of operators (dimension 6) which presumes the SU(2)×U(1) gauge symmetry is broken by means other than the conventional Higgs scalar doublet [1–3]. In this representation possible quartic couplings, a_0, a_c, a_n, are expressed in terms of the following dimension-6 operators [1,2];

$$L_6^0 = -\tfrac{e^2}{16\Lambda^2}\, a_0\, F^{\mu\nu}\, F_{\mu\nu}\vec{W}^{\alpha}\cdot\vec{W}_{\alpha}$$
$$L_6^c = -\tfrac{e^2}{16\Lambda^2}\, a_c\, F^{\mu\alpha}\, F_{\mu\beta}\vec{W}^{\beta}\cdot\vec{W}_{\alpha}$$
$$L_6^n = -i\tfrac{e^2}{16\Lambda^2}\, a_n\epsilon_{ijk}\, W_{\mu\alpha}^{(i)}\, W_{\nu}^{(j)}\, W^{(k)\alpha}F^{\mu\nu}$$
$$\widetilde{L}_6^0 = -\tfrac{e^2}{16\Lambda^2}\, \widetilde{a}_0\, F^{\mu\nu}\, \widetilde{F}_{\mu\nu}\vec{W}^{\alpha}\cdot\vec{W}_{\alpha}$$
$$\widetilde{L}_6^n = -i\tfrac{e^2}{16\Lambda^2}\, \widetilde{a}_n\epsilon_{ijk}\, W_{\mu\alpha}^{(i)}\, W_{\nu}^{(j)}\, W^{(k)\alpha}\widetilde{F}^{\mu\nu}$$

where F, W are photon and W fields, L_6^0 and L_6^c conserve C, P separately ($\widetilde{L}_6^0$ conserves only C) and generate anomalous $W^+W^-\gamma\gamma$ and $ZZ\gamma\gamma$ couplings, L_6^n violates CP ($\widetilde{L}_6^n$ violates both C and P) and generates an anomalous $W^+W^-Z\gamma$ coupling, and Λ is an energy scale for new physics. For the $ZZ\gamma\gamma$ coupling the CP-violating term represented by L_6^n does not contribute. These couplings are assumed to be real and to vanish at tree level in the Standard Model.

Within the same framework as above, a more recent description of the quartic couplings [3] treats the anomalous parts of the $WW\gamma\gamma$ and $ZZ\gamma\gamma$ couplings separately, leading to two sets parametrized as a_0^V/Λ^2 and a_c^V/Λ^2, where $V = W$ or Z.

With the discovery of a Higgs at the LHC in 2012, it is then useful to go to the next higher dimensional representation (dimension 8 operators) in which the gauge symmetry is broken by the conventional Higgs scalar doublet [3,4]. There are 14 operators which can contribute to the anomalous quartic coupling signal. Some of the operators have analogues in the dimension 6 scheme. The CMS collaboration, [5], have used this parametrization, in which the connections between the two schemes are also summarized:

$$\begin{aligned}\mathcal{L}_{AQGC} = &-\frac{e^2}{8}\frac{a_0^W}{\Lambda^2}F_{\mu\nu}F^{\mu\nu}W^{+a}W_a^- \\ &-\frac{e^2}{16}\frac{a_c^W}{\Lambda^2}F_{\mu\nu}F^{\mu a}(W^{+\nu}W_a^- + W^{-\nu}W_a^+) \\ &-e^2g^2\frac{\kappa_0^W}{\Lambda^2}F_{\mu\nu}Z^{\mu\nu}W^{+a}W_a^- \\ &-\frac{e^2g^2}{2}\frac{\kappa_c^W}{\Lambda^2}F_{\mu\nu}Z^{\mu a}(W^{+\nu}W_a^- + W^{-\nu}W_a^+) \\ &+\frac{f_{T,0}}{\Lambda^4}Tr[\widehat{W}_{\mu\nu}\widehat{W}^{\mu\nu}]\times Tr[\widehat{W}_{\alpha\beta}\widehat{W}^{\alpha\beta}]\end{aligned}$$

The energy scale of possible new physics is Λ, and $g = e/sin(\theta_W)$, e being the unit electric charge and θ_W the Weinberg angle. The field tensors are described in [3,4].

The two dimension 6 operators a_0^W/Λ^2 and a_c^W/Λ^2 are associated with the $WW\gamma\gamma$ vertex. Among dimension 8 operators, κ_0^W/Λ^2 and κ_c^W/Λ^2 are associated with the $WWZ\gamma$ vertex, whereas the parameter $f_{T,0}/\Lambda^4$ contributes to both vertices. There is a relationship between these two dimension 6 parameters and the dimension 8 parameters $f_{M,i}/\Lambda^4$ as follows [3]:

$$\frac{a_0^W}{\Lambda^2} = -\frac{4M_W^2}{g^2}\frac{f_{M,0}}{\Lambda^4} - \frac{8M_W^2}{g'^2}\frac{f_{M,2}}{\Lambda^4}$$

$$\frac{a_c^W}{\Lambda^2} = -\frac{4M_W^2}{g^2}\frac{f_{M,1}}{\Lambda^4} - \frac{8M_W^2}{g'^2}\frac{f_{M,3}}{\Lambda^4}$$

where $g' = e/cos(\theta_W)$ and M_W is the invariant mass of the W boson. This relation provides a translation between limits on dimension 6 operators $a_{0,c}^W$ and $f_{M,j}/\Lambda^4$. It is further required [4] that $f_{M,0} = 2f_{M,2}$ and $f_{M,1} = 2f_{M,3}$ which suppresses contributions to the $WWZ\gamma$ vertex. The complete set of Lagrangian contributions as presented in [4] corresponds to 19 anomalous couplings in total – $f_{S,i},\ i = 1, 2$, $f_{M,i},\ i = 0, \ldots, 8$ and $f_{T,i}, i = 0, \ldots, 9$ – each scaled by $1/\Lambda^4$.

Another approach to couplings is the so called K-matrix framework [7], in which the anomalous couplings can be expressed in terms of two parameters α_4 and α_5, which account for all BSM effects.

The LHC collaborations have published couplings results based on various theoretical frameworks. It is hoped that the collaborations will agree to use at least one common set of parameters to express these limits to enable the reader to make a comparison, and to allow for a possible LHC combination.

a_0/Λ^2, a_c/Λ^2

Combining published and unpublished preliminary LEP results the following 95% CL intervals for the QGCs associated with the $ZZ\gamma\gamma$ vertex are derived (CERN-PH-EP/2005-051 or hep-ex/0511027):

$$-0.008 < a_0^Z/\Lambda^2 < +0.021$$
$$-0.029 < a_c^Z/\Lambda^2 < +0.039$$

Anomalous Z quartic couplings have also been measured by the Tevatron and LHC experiments. As discussed in the review on "Anomalous WW/ZZ quartic couplings," the coupling parameters in the Anomalous QGC Lagrangian may relate to processes involving only the W or only to the Z or to both. Thus, results on all other AQGCs are reported together in the W listings.

• • • We do not use the following data for averages, fits, limits, etc. • • •		
	[1] ABBIENDI 04L	OPAL
	[2] HEISTER 04A	ALEP
	[3] ACHARD 02G	L3

[1] ABBIENDI 04L select 20 $e^+e^- \to \nu\overline{\nu}\gamma\gamma$ acoplanar events in the energy range 180–209 GeV and 176 $e^+e^- \to q\overline{q}\gamma\gamma$ events in the energy range 130–209 GeV. These samples

are used to constrain possible anomalous $W^+W^-\gamma\gamma$ and $ZZ\gamma\gamma$ quartic couplings. Further combining with the $W^+W^-\gamma$ sample of ABBIENDI 04B the following one–parameter 95% CL limits are obtained: $-0.007 < a_0^Z/\Lambda^2 < 0.023$ GeV^{-2}, $-0.029 < a_C^Z/\Lambda^2 < 0.029$ GeV^{-2}, $-0.020 < a_0^W/\Lambda^2 < 0.020$ GeV^{-2}, $-0.052 < a_C^W/\Lambda^2 < 0.037$ GeV^{-2}.

[2] In the CM energy range 183 to 209 GeV HEISTER 04A select 30 $e^+e^- \to \nu\overline{\nu}\gamma\gamma$ events with two acoplanar, high energy and high transverse momentum photons. The photon–photon acoplanarity is required to be $> 5^\circ$, $E_\gamma/\sqrt{s} > 0.025$ (the more energetic photon having energy $> 0.2\sqrt{s}$), $p_{T_\gamma}/E_{\rm beam} > 0.05$ and $|\cos\theta_\gamma| < 0.94$. A likelihood fit to the photon energy and recoil missing mass yields the following one–parameter 95% CL limits: $-0.012 < a_0^Z/\Lambda^2 < 0.019$ GeV^{-2}, $-0.041 < a_C^Z/\Lambda^2 < 0.044$ GeV^{-2}, $-0.060 < a_0^W/\Lambda^2 < 0.055$ GeV^{-2}, $-0.099 < a_C^W/\Lambda^2 < 0.093$ GeV^{-2}.

[3] ACHARD 02G study $e^+e^- \to Z\gamma\gamma \to q\overline{q}\gamma\gamma$ events using data at center-of-mass energies from 200 to 209 GeV. The photons are required to be isolated, each with energy >5 GeV and $|\cos\theta| < 0.97$, and the di-jet invariant mass to be compatible with that of the Z boson (74–111 GeV). Cuts on Z velocity ($\beta < 0.73$) and on the energy of the most energetic photon reduce the backgrounds due to non-resonant production of the $q\overline{q}\gamma\gamma$ state and due to ISR respectively, yielding a total of 40 candidate events of which 8.6 are expected to be due to background. The energy spectra of the least energetic photon are fitted for all ten center-of-mass energy values from 130 GeV to 209 GeV (as obtained adding to the present analysis 130–202 GeV data of ACCIARRI 01E, for a total of 137 events with an expected background of 34.1 events) to obtain the fitted values $a_0/\Lambda^2 = 0.00^{+0.02}_{-0.01}$ GeV^{-2} and $a_C/\Lambda^2 = 0.03^{+0.01}_{-0.02}$ GeV^{-2}, where the other parameter is kept fixed to its Standard Model value (0). A simultaneous fit to both parameters yields the 95% CL limits -0.02 GeV$^{-2} < a_0/\Lambda^2 < 0.03$ GeV^{-2} and -0.07 GeV$^{-2} < a_C/\Lambda^2 < 0.05$ GeV^{-2}.

H

$J = 0$

was H^0

In the following H refers to the signal that has been discovered in the Higgs searches. Whereas the observed signal is labeled as a spin 0 particle and is called a Higgs Boson, the detailed properties of H and its role in the context of electroweak symmetry breaking need to be further clarified. These issues are addressed by the measurements listed below.

Concerning mass limits and cross section limits that have been obtained in the searches for neutral and charged Higgs bosons, see the sections "Searches for Neutral Higgs Bosons" and "Searches for Charged Higgs Bosons ($H^{\pm}$ and $H^{\pm\pm}$)", respectively.

[1] AAD 23BP combine 13 TeV results of $H \to \gamma\gamma$ (AAD 23BU) and $H \to ZZ^* \to 4\ell$ where $\ell = e,\ \mu$ (AAD 23AU) using 140 fb^{-1} of pp collision data. The result is 125.10 ± 0.09(stat)±0.07(syst) GeV.

[2] SIRUNYAN 20L result of $H \to \gamma\gamma$ is combined with that of $H \to ZZ^* \to 4\ell$ where $\ell = e,\ \mu$ (SIRUNYAN 17AV).

[3] Combined value from $\gamma\gamma$ and $ZZ^* \to 4\ell$ final states.

[4] ATLAS and CMS data are fitted simultaneously.

[5] AAD 23AU use 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV with $H \to ZZ^* \to 4\ell$ where $\ell = e,\ \mu$.

[6] AAD 23AU combine 13 TeV results with 7 and 8 TeV results (AAD 14W).

[7] AAD 23BP combine 13 TeV results with 7 and 8 TeV results. The result is 125.11 ± 0.09(stat)±0.06(syst) GeV.

[8] AAD 23BU use 140 fb^{-1} of pp collisions at E_{cm} = 13 TeV with $H \to \gamma\gamma$.

[9] AAD 23BU combine 13 TeV results with 7 and 8 TeV results (AAD 15B).

[10] SIRUNYAN 20L use 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV with $H \to \gamma\gamma$.

[11] SIRUNYAN 20L combine 13 TeV results with 7 and 8 TeV results (KHACHATRYAN 15AM).

[12] AABOUD 18BM use 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV with $H \to ZZ^* \to 4\ell$ where $\ell = e,\ \mu$.

[13] AABOUD 18BM use 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV with $H \to \gamma\gamma$.

[14] AABOUD 18BM combine 13 TeV results with 7 and 8 TeV results. Other combined results are summarized in their Fig. 4.

[15] SIRUNYAN 17AV use 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV with $H \to ZZ^* \to 4\ell$ where $\ell = e,\ \mu$.

[16] KHACHATRYAN 15AM use up to 5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and up to 19.7 fb^{-1} at E_{cm} = 8 TeV.

[17] AAD 14W use 4.5 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 20.3 fb^{-1} at 8 TeV.

[18] CHATRCHYAN 14AA use 5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.7 fb^{-1} at E_{cm} = 8 TeV.

[19] CHATRCHYAN 14K use 4.9 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.7 fb^{-1} at E_{cm} = 8 TeV.

[20] KHACHATRYAN 14P use 5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.7 fb^{-1} at E_{cm} = 8 TeV.

[21] AAD 13AK use 4.7 fb^{-1} of pp collisions at E_{cm}=7 TeV and 20.7 fb^{-1} at E_{cm}=8 TeV. Superseded by AAD 14W.

[22] CHATRCHYAN 13J use 5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 12.2 fb^{-1} at E_{cm} = 8 TeV.

[23] AAD 12AI obtain results based on 4.6–4.8 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 5.8–5.9 fb^{-1} at E_{cm} = 8 TeV. An excess of events over background with a local significance of 5.9 σ is observed at m_H = 126 GeV. See also AAD 12DA.

[24] CHATRCHYAN 12N obtain results based on 4.9–5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 5.1–5.3 fb^{-1} at E_{cm} = 8 TeV. An excess of events over background with a local significance of 5.0 σ is observed at about m_H = 125 GeV. See also CHATRCHYAN 12BY and CHATRCHYAN 13Y.

H SPIN AND *CP* PROPERTIES

The observation of the signal in the $\gamma\gamma$ final state rules out the possibility that the discovered particle has spin 1, as a consequence of the Landau-Yang theorem. This argument relies on the assumptions that the decaying particle is an on-shell resonance and that the decay products are indeed two photons rather than two pairs of boosted photons, which each could in principle be misidentified as a single photon.

Concerning distinguishing the spin 0 hypothesis from a spin 2 hypothesis, some care has to be taken in modelling the latter in order to ensure that the discriminating power is actually based on the spin properties rather than on unphysical behavior that may affect the model of the spin 2 state.

Under the assumption that the observed signal consists of a single state rather than an overlap of more than one resonance, it is sufficient to discriminate between distinct hypotheses in the spin analyses. On the other hand, the determination of the *CP* properties is in general much more difficult since in principle the observed state could consist of any admixture of *CP*-even and *CP*-odd components. As a first step, the compatibility of the data with distinct hypotheses of pure *CP*-even and pure *CP*-odd states with different spin assignments has been investigated. In order to treat the case of a possible mixing of different *CP* states, certain cross section ratios are considered. Those cross section ratios need to be distinguished from the amount of mixing between a *CP*-even and a *CP*-odd state, as the cross section ratios depend in addition also on the coupling strengths of the *CP*-even and *CP*-odd components to the involved particles. A small relative coupling implies a small sensitivity of the corresponding cross section ratio to effects of *CP* mixing.

[1] AAD 23AK measure the *CP* structure of the τ Yukawa coupling using 139 fb^{-1} of data at E_{cm} = 13 TeV. The *CP*-mixing angle α for τ Yukawa coupling is measured to be $9 \pm 16^\circ$. The data disfavour the pure *CP*-odd ($\alpha = 90^\circ$) at 3.4 σ.

[2] AAD 23AN test *CP* invariance in H production via VBF using $H \to \gamma\gamma$ decay channel with 139 fb^{-1} at E_{cm} = 13 TeV. By using the Optimal Observable method, the data constrain parameters describing the strength of the *CP*-odd component in the coupling between Higgs and W/Z in effective field theory bases: $\tilde{d}$ in the HISZ basis and $c_{H\widetilde{W}}$ in the Warsaw basis. The result is -0.010 $\leq \tilde{d} \leq$ 0.040 and -0.15 $\leq c_{H\widetilde{W}} \leq$ 0.67 at 68% CL. See their Table I, which shows the result combined with $H \to \tau\tau$ (AAD 20N): -0.012 $\leq \tilde{d} \leq$ 0.030 at 68% CL.

[3] TUMASYAN 23AJ constraint anomalous couplings of the Higgs to vector bosons and fermions using $pp \to H \to \tau\tau$ at E_{cm} = 13 TeV with 138 fb^{-1} data. The *CP*-violating parameter in gluon-fusion production f_{a3}^{ggH} and the effective mixing angle α^{Hff} are given in their Table VII with $H \to \tau\tau$ and f_{a3}^{ggH} in their Table X with $H \to \tau\tau$ and $H \to 4\ell$. Using the VBF production analysis, the *CP*-violating parameter f_{a3} and the *CP*-conserving parameters f_{a2}, $f_{\Lambda1}$ and $f_{\Lambda1}^{Z\gamma}$ are given in their Table VIII with $H \to \tau\tau$ and Table IX with $H \to \tau\tau$ and $H \to 4\ell$. The *CP*-violating parameter f_{CP}^{Htt} is constrained to be $0.03^{+0.17}_{-0.03}$ using $H \to \tau\tau$, $H \to 4\ell$ and $H \to \gamma\gamma$.

[4] TUMASYAN 23P constrain $\tilde{\kappa}_t$ from $t\bar{t}H$ and tH decaying $H \to WW^*$ and $H \to \tau\tau$ (multilepton decay mode) with 138 fb^{-1} pp collision data at E_{cm} = 13 TeV. The $\tilde{\kappa}_t$ is constrained to be $|\tilde{\kappa}_t| \leq$ 1.4 at 95% CL by fixing κ_t = 1 and other couplings (κ_V etc.) to the SM values, see their Table 6 (see their Fig. 9 for 2-dim contours). The fractional contribution of the *CP*-odd component $|f_{CP}^{Htt}|$ is constrained to (0.24, 0.81) at 68% CL with a best fit value of 0.59. The combination with other $t\bar{t}H$ decaying $H \to \gamma\gamma$ (SIRUNYAN 20AS) and $H \to 4\ell$ (SIRUNYAN 21AE) constraints to be $|\tilde{\kappa}_t| \leq$ 1.07 at 95% CL and $|f_{CP}^{Htt}| <$0.55 at 68% CL with a best fit value of 0.28.

[5] AAD 22V measure the *CP* properties of the effective Higgs-gluon interaction using gluon fusion $H \to WW^* \to e\nu\mu\nu$ plus two jets with 36.1 fb^{-1} of data at E_{cm} = 13 TeV. The measured tangent of the *CP*-mixing angle $\tan\alpha$ is 0.0 $\pm$ 0.4 $\pm$ 0.3 assuming the standard model HVV couplings. See their Fig. 6.

[6] TUMASYAN 22Y measure the *CP* structure of the τ Yukawa coupling using 137 fb^{-1} of data at E_{cm} = 13 TeV. The *CP*-mixing angle α for τ Yukawa coupling is measured to be $-1 \pm 19^\circ$. The data disfavour the pure *CP*-odd ($\alpha = 90^\circ$) at 3.0 σ.

[7] AAD 20N test *CP* invariance in H production via VBF using $H \to \tau\tau$ decay channel with 36.1 fb^{-1} at E_{cm} = 13 TeV. By using the Optimal Observable method, the data constrain a parameter $\tilde{d}$, which is for the strength of *CP* violation in an effective field theory, to be $-0.090 \leq \tilde{d} \leq 0.035$ at 68% CL (see their Fig. 6).

[8] AAD 20Z exclude a *CP*-mixing angle α, $|\alpha| > 43^\circ$ at 95% CL, where $\alpha = 0$ represents the Standard Model, in 139 fb^{-1} of data at E_{cm} = 13 TeV. The pure *CP*-odd structure of the top Yukawa coupling ($\alpha = 90^\circ$) is excluded at 3.9 σ.

[9] SIRUNYAN 20AS exclude the pure *CP*-odd structure of the top Yukawa coupling at 3.2 σ using $t\bar{t}H$, $H \to \gamma\gamma$ in 137 fb^{-1} of data at E_{cm} = 13 TeV. The fractional contribution of the *CP*-odd component $f_{CP}^{t\bar{t}H}$ is measured to be 0.00 $\pm$ 0.33.

[10] SIRUNYAN 19BL measure the anomalous HVV couplings from on-shell and off-shell production in the 4ℓ final state. Data of 80.2 fb^{-1} at 13 TeV, 19.7 fb^{-1} at 8 TeV, and 5.1 fb^{-1} at 7 TeV are used. See their Tables VI and VII for anomalous HVV couplings of *CP*-violating and *CP*-conserving parameters with on- and off-shells.

[11] SIRUNYAN 19BZ constrain anomalous HVV couplings of the Higgs boson with data of 35.9 fb^{-1} at E_{cm} = 13 TeV using Higgs boson candidates with two jets produced in VBF, ggF, and VH that decay to $\tau\tau$. See their Table 2 and Fig. 10, which show 68% CL and 95% CL intervals. Combining those with the $H \to 4\ell$ (SIRUNYAN 19BL, on-shell scenario), results shown in their Tables 3, 4, and Fig. 11 are obtained. A *CP*-violating parameter is set to be $f_{a3}\cos(\phi_{a3}) = (0.00 \pm 0.27) \times 10^{-3}$ and *CP*-conserving parameters are $f_{a2}\cos(\phi_{a2}) = (0.08^{+1.04}_{-0.21}) \times 10^{-3}$, $f_{\Lambda1}\cos(\phi_{\Lambda1}) = (0.00^{+0.53}_{-0.09}) \times 10^{-3}$, and $f_{\Lambda1}^{Z\gamma}\cos(\phi_{\Lambda1}^{Z\gamma}) = (0.0^{+1.1}_{-1.3}) \times 10^{-3}$.

[12] AABOUD 18AJ study the tensor structure of the Higgs boson couplings using an effective Lagrangian using 36.1 fb^{-1} of pp collision data at E_{cm} = 13 TeV. Constraints are set on the non-Standard-Model *CP*-even and *CP*-odd couplings to Z bosons and on the *CP*-odd coupling to gluons. See their Figs. 9 and 10, and Tables 10 and 11.

[13] SIRUNYAN 17AM constrain anomalous couplings of the Higgs boson with 5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV, 19.7 fb^{-1} at E_{cm} = 8 TeV, and 38.6 fb^{-1} at E_{cm} = 13 TeV. See their Table 3 and Fig. 3, which show 68% CL and 95% CL intervals. A *CP* violation parameter f_{a3} is set to be $f_{a3}\cos(\phi_{a3}) = [-0.38, 0.46]$ at 95% CL ($\phi_{a3} = 0$ or π).

[14] AAD 16 study $H \to \gamma\gamma$ with an effective Lagrangian including *CP* even and odd terms in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. The data is consistent with the expectations for the Higgs boson of the Standard Model. Limits on anomalous couplings are also given.

[15] AAD 16BL study VBF $H \to \tau\tau$ with an effective Lagrangian including a *CP* odd term in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. The measurement is consistent with the expectation of the Standard Model. The *CP*-mixing parameter $\tilde{d}$ (a dimensionless coupling $\tilde{d} = -(m_W^2/\Lambda^2) f_{\widetilde{WW}}$) is constrained to the interval of (-0.11, 0.05) at 68% CL under the assumption of $\tilde{d} = \tilde{d}_B$.

[16] KHACHATRYAN 16AB search for anomalous pseudoscalar couplings of the Higgs boson to W and Z with 18.9 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Table 5 and Figs 5 and 6 for limits on possible anomalous pseudoscalar coupling parameters.

[17] AAD 15AX compare the $J^{CP} = 0^+$ Standard Model assignment with other J^{CP} hypotheses in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV, using the process $H \to WW^* \to e\nu\mu\nu$. 2^+ hypotheses are excluded at 84.5–99.4%CL, 0^- at 96.5%CL, 0^+ (field strength coupling) at 70.8%CL. See their Fig. 19 for limits on possible *CP* mixture parameters.

[18] AAD 15CI compare the $J^{CP} = 0^+$ Standard Model assignment with other J^{CP} hypotheses in 4.5 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 20.3 fb^{-1} at E_{cm} = 8 TeV, using the processes $H \to ZZ^* \to 4\ell$. $H \to \gamma\gamma$ and combine with AAD 15AX data. 0^+ (field strength coupling), 0^- and several 2^+ hypotheses are excluded at more than 99.9% CL. See their Tables 7–9 for limits on possible *CP* mixture parameters.

[19] AALTONEN 15 combine AALTONEN 15B and ABAZOV 14F data. An upper limit of 0.36 of the Standard Model production rate at 95% CL is obtained both for a 0^- and a 2^+ state. Assuming the SM event rate, the $J^{CP} = 0^-$ (2^+) hypothesis is excluded at the 5.0σ (4.9σ) level.

[20] AALTONEN 15B compare the $J^{CP} = 0^+$ Standard Model assignment with other J^{CP} hypotheses in 9.45 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV, using the processes $ZH \to \ell\ell b\overline{b}$, $WH \to \ell\nu b\overline{b}$, and $ZH \to \nu\nu b\overline{b}$. Bounds on the production rates of 0^- and 2^+ (graviton-like) states are set, see their tables II and III.

[21] KHACHATRYAN 15Y compare the $J^{CP} = 0^+$ Standard Model assignment with other J^{CP} hypotheses in up to 5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and up to 19.7 fb^{-1} at E_{cm} = 8 TeV, using the processes $H \to 4\ell$, $H \to WW^*$, and $H \to \gamma\gamma$. 0^- is excluded at 99.98% CL, and several 2^+ hypotheses are excluded at more than 99% CL. Spin 1 models are excluded at more than 99.999% CL in ZZ^* and WW^* modes. Limits on anomalous couplings and several cross section fractions, treating the case of *CP*-mixed states, are also given.

[22] ABAZOV 14F compare the $J^{CP} = 0^+$ Standard Model assignment with $J^{CP} = 0^-$ and 2^+ (graviton-like coupling) hypotheses in up to 9.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. They use kinematic correlations between the decay products of the vector boson and the Higgs boson in the final states $ZH \to \ell\ell b\overline{b}$, $WH \to \ell\nu b\overline{b}$, and $ZH \to$

$\nu\nu b\overline{b}$. The 0^- (2^+) hypothesis is excluded at 97.6% CL (99.0% CL). In order to treat the case of a possible mixture of a 0^+ state with another J^{CP} state, the cross section fractions $f_X = \sigma_X/(\sigma_{0^+} + \sigma_X)$ are considered, where $X = 0^-$, 2^+. Values for f_{0^-} (f_{2^+}) above 0.80 (0.67) are excluded at 95% CL under the assumption that the total cross section is that of the SM Higgs boson.

[23] CHATRCHYAN 14AA compare the $J^{CP} = 0^+$ Standard Model assignment with various J^{CP} hypotheses in 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV. $J^{CP} = 0^-$ and $1^\pm$ hypotheses are excluded at 99% CL, and several $J = 2$ hypotheses are excluded at 95% CL. In order to treat the case of a possible mixture of a 0^+ state with another J^{CP} state, the cross section fraction $f_{a3} = |a_3|^2\,\sigma_3\,/\,(|a_1|^2\,\sigma_1 + |a_2|^2\,\sigma_2 + |a_3|^2\,\sigma_3)$ is considered, where the case $a_3 = 1$, $a_1 = a_2 = 0$ corresponds to a pure CP-odd state. Assuming $a_2 = 0$, a value for f_{a3} above 0.51 is excluded at 95% CL.

[24] CHATRCHYAN 14G compare the $J^{CP} = 0^+$ Standard Model assignment with $J^{CP} = 0^-$ and 2^+ (graviton-like coupling) hypotheses in 4.9 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.4 fb^{-1} at $E_{cm} = 8$ TeV. Varying the fraction of the production of the 2^+ state via gg and $q\overline{q}$, 2^+ hypotheses are disfavored at CL between 83.7 and 99.8%. The 0^- hypothesis is disfavored against 0^+ at the 65.3% CL.

[25] KHACHATRYAN 14P compare the $J^{CP} = 0^+$ Standard Model assignment with a 2^+ (graviton-like coupling) hypothesis in 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV. Varying the fraction of the production of the 2^+ state via gg and $q\overline{q}$, 2^+ hypotheses are disfavored at CL between 71 and 94%.

[26] AAD 13AJ compare the spin 0, CP-even hypothesis with specific alternative hypotheses of spin 0, CP-odd, spin 1, CP-even and CP-odd, and spin 2, CP-even models using the Higgs boson decays $H \to \gamma\gamma$, $H \to ZZ^* \to 4\ell$ and $H \to WW^* \to \ell\nu\ell\nu$ and combinations thereof. The data are compatible with the spin 0, CP-even hypothesis, while all other tested hypotheses are excluded at confidence levels above 97.8%.

[27] CHATRCHYAN 13J study angular distributions of the lepton pairs in the ZZ^* channel where both Z bosons decay to e or μ pairs. Under the assumption that the observed particle has spin 0, the data are found to be consistent with the pure CP-even hypothesis, while the pure CP-odd hypothesis is disfavored.

H DECAY WIDTH

The total decay width for a light Higgs boson with a mass in the observed range is not expected to be directly observable at the LHC. For the case of the Standard Model the prediction for the total width is about 4 MeV, which is three orders of magnitude smaller than the experimental mass resolution. There is no indication from the results observed so far that the natural width is broadened by new physics effects to such an extent that it could be directly observable. Furthermore, as all LHC Higgs channels rely on the identification of Higgs decay products, the total Higgs width cannot be measured indirectly without additional assumptions. The different dependence of on-peak and off-peak contributions on the total width in Higgs decays to ZZ^* and interference effects between signal and background in Higgs decays to $\gamma\gamma$ can provide additional information in this context. Constraints on the total width from the combination of on-peak and off-peak contributions in Higgs decays to ZZ^* rely on the assumption of equal on- and off-shell effective couplings. Without an experimental determination of the total width or further theoretical assumptions, only ratios of couplings can be determined at the LHC rather than absolute values of couplings.

[1] AAD 23BR use 139 fb^{-1} at $E_{cm} = 13$ TeV. The off-shell Higgs boson production in the $ZZ \to 4\ell$ and $ZZ \to 2\ell2\nu$ decay channels and the on-shell production in the $ZZ^* \to 4\ell$ ($\ell = e$, μ, AAD 20AQ) decay channels are used to measure the total width. The off-shell Higgs signal strength is measured to be $1.1^{+0.7}_{-0.6}$ assuming the same on-shell and off-shell coupling modifiers are used individually for gluon-fusion and for gauge-boson modes. The scenario of no off-shell contribution is excluded at 3.3 σ. Combining with the on-shell signal strength measurement, the total width normalized to its SM expectation Γ_H/Γ_H^{SM} is measured to be $1.1^{+0.7}_{-0.6}$ assuming the same on-shell and off-shell coupling modifiers are used individually for gluon-fusion and for gauge-boson modes. The observed upper limit on the total width is 10.5 MeV at 95% CL. See their Fig. 7.

[2] TUMASYAN 22AM use up to 140 fb^{-1} at $E_{cm} = 13$ TeV. The off-shell Higgs boson production in the $ZZ \to 4\ell$ and $ZZ \to 2\ell2\nu$ decay channels and the on-shell production in the $ZZ^* \to 4\ell$ ($\ell = e$, μ) decay channels are used to measure the total width. The off-shell Higgs signal strength is measured to be $0.62^{+0.68}_{-0.45}$ without the constraint on the ratio of the off-shell signal strengths for gluon-fusion and gauge-boson modes. The scenario of no off-shell contribution is excluded at 3.6 σ. The results are shown in their Table 1 with other constraint scenarios and the decay widths assuming the same coupling modifiers for on- and off-shell couplings (g_p and g_d in their notation). The measurement of anomalous HVV couplings is shown in their Extended Data Table 1 and Fig. 8.

[3] SIRUNYAN 19BL measure the width and anomalous HVV couplings from on-shell and off-shell production in the 4ℓ final state. Data of 80.2 fb^{-1} at 13 TeV, 19.7 fb^{-1} at 8 TeV, and 5.1 fb^{-1} at 7 TeV are used. The total width for the SM-like couplings is measured to be also [0.08, 9.16] MeV with 95% CL, assuming SM-like couplings for on- and off-shells (see their Table VIII). Constraints on the total width for anomalous HVV interaction cases are found in their Table IX. See their Table X for the Higgs boson signal strength in the off-shell region.

[4] AABOUD 18BP use 36.1 fb^{-1} at $E_{cm} = 13$ TeV. An observed upper limit on the off-shell Higgs signal strength of 3.8 is obtained at 95% CL using off-shell Higgs boson production in the $ZZ \to 4\ell$ and $ZZ \to 2\ell2\nu$ decay channels ($\ell = e$, μ). Combining with the on-shell signal strength measurements, the quoted upper limit on the Higgs boson total width is obtained, assuming the ratios of the relevant Higgs-boson couplings to the SM predictions are constant with energy from on-shell production to the high-mass range.

[5] SIRUNYAN 17AV obtain an upper limit on the width from the $m_{4\ell}$ distribution in $ZZ^* \to 4\ell$ ($\ell = e$, μ) decays. Data of 35.9 fb^{-1} pp collisions at $E_{cm} = 13$ TeV is used. The expected limit is 1.60 GeV.

[6] KHACHATRYAN 16BA derive constraints on the total width from comparing $WW^{(*)}$ production via on-shell and off-shell H using 4.9 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.4 fb^{-1} at 8 TeV.

[7] KHACHATRYAN 16BA combine the $WW^{(*)}$ result with $ZZ^{(*)}$ results of KHACHATRYAN 15BA and KHACHATRYAN 14D.

[8] AAD 15BE derive constraints on the total width from comparing $ZZ^{(*)}$ and $WW^{(*)}$ production via on-shell and off-shell H using 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. The K factor for the background processes is assumed to be equal to that for the signal.

[9] KHACHATRYAN 15AM combine $\gamma\gamma$ and $ZZ^* \to 4\ell$ results. The expected limit is 2.3 GeV.

[10] KHACHATRYAN 15BA derive a lower limit on the total width from an upper limit on the decay flight distance $\tau < 1.9 \times 10^{-13}$ s. 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at 8 TeV are used.

[11] KHACHATRYAN 15BA derive constraints on the total width from comparing $ZZ^{(*)}$ production via on-shell and off-shell H with an unconstrained anomalous coupling. 4ℓ final states in 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV are used.

[12] AAD 14W use 4.5 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.3 fb^{-1} at 8 TeV. The expected limit is 6.2 GeV.

[13] CHATRCHYAN 14AA use 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV. The expected limit is 2.8 GeV.

[14] KHACHATRYAN 14D derive constraints on the total width from comparing $ZZ^{(*)}$ production via on-shell and off-shell H. 4ℓ and $\ell\ell\nu\nu$ final states in 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV are used.

[15] KHACHATRYAN 14P use 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV. The expected limit is 3.1 GeV.

[1] TUMASYAN 23C search for $H\to\ \Upsilon(nS)\Upsilon(mS)$ with $\Upsilon(nS)$, $\Upsilon(mS)\to\ \mu^+\mu^-$ (n, m = 1, 2, 3) with 138 fb^{-1} of pp collision data at $E_{cm}=13$ TeV. The quoted value is for the Higgs decays for longitudinally polarized mesons. See their Table 1 for other cases.
[2] SIRUNYAN 19BR search for $H\to\ \Upsilon(nS)\Upsilon(mS)$ with $\Upsilon(nS),\Upsilon(mS)\to\ \mu^+\mu^-$ (n, m = 1, 2, 3) for 37.5 fb^{-1} of pp collision data at $E_{cm}=13$ TeV. Υs from the Higgs decay are assumed to be unpolarized. For fully longitudinal (transverse) polarized Υs, limits change by -22% ($+10\%$). The three Υ states selected in a mass range of 8.5–11 GeV are not distinguished.

[1] AAD 23A report the combined results of 7, 8 (AAD 15CX) and 13 TeV assuming the Standard Model cross section ($m_H = 125$ GeV). See their Table 1 and Fig. 3.

[2] AAD 23A report the combined results using 139 fb^{-1} of data at $E_{cm} = 13$ TeV, where H decaying to invisible final states in VBF (AAD 22P), ZH, $Z \to ee$, $\mu\mu$ (AAD 22D), $pp \to t\bar{t}H$ (AAD 23AF), VBF+γ (AAD 22S) and gluon-fusion production with an energetic jet (AAD 21F) assuming the Standard Model cross section ($m_H = 125$ GeV). See their Table 1 and Fig. 3.

[3] AAD 23AF search for $pp \to t\bar{t}H$ with H decaying to invisible final states using 139 fb^{-1} of data. The quoted limit on the branching ratio is given for $m_H = 125$ GeV and assumes the Standard Model cross section. See their Table 3 for different decay topologies.

[4] TUMASYAN 23BA search for H decaying to invisible final states produced in association with a $t\bar{t}$ or a V, which decay to a fully hadronic final state. 138 fb^{-1} of data is used. The quoted limit on the branching ratio is given for $m_H = 125$ GeV and assumes the Standard Model cross section. See their Fig. 6 for the results of individual topologies.

[5] TUMASYAN 23BA report the combined results of 7, 8, and 13 TeV assuming the Standard Model cross section ($m_H = 125$ GeV). They combine results from TUMASYAN 22G, SIRUNYAN 21A, SIRUNYAN 21B, TUMASYAN 21D, SIRUNYAN 20AH, KHACHATRYAN 17F, CHATRCHYAN 14B as shown in their Table 8. See their Fig. 7 and Table 9 for the results of individual topologies.

[6] AAD 22D search for H decaying to invisible final states associated with a Z decaying $ee/\mu\mu$ using 139 fb^{-1} at 13 TeV. The limit is obtained for $m_H = 125$ GeV and assuming the SM ZH production cross section. The branching ratio is obtained to be $(0.3 \pm 9.0)\%$.

[7] AAD 22P search for $pp \to qqHX$ (VBF) with H decaying to invisible final states using 139 fb^{-1} of data. The quoted limit on the branching ratio is given for $m_H = 125$ GeV and assumes the Standard Model cross section.

[8] AAD 22S observe electroweak $Z(\to \nu\nu)\gamma$+2jets production process with 139 fb^{-1} of data. This result is applicable to search for $pp \to qqH\gamma X$ (VBF+γ) with H decaying to invisible final states. The quoted limit on the branching ratio is given for $m_H = 125$ GeV and assumes the Standard Model cross section.

[9] ATLAS 22 report the combined results using 139 fb^{-1} of data at $E_{cm} = 13$ TeV, where H decaying to invisible final states in VBF (AAD 22P), and ZH, $Z \to ee$, $\mu\mu$ (AAD 22D), assuming $\kappa_V \leq 1$ and $B_{undetected} \geq 0$.

[10] CMS 22 report the combined results using (a part of) 138 fb^{-1} of data at $E_{cm} = 13$ TeV, where H decaying to invisible final states in VBF (SIRUNYAN 19BO), associated with an energetic jet or a $V(\to q\bar{q})$ (TUMASYAN 21D), and ZH, $Z \to ee$, $\mu\mu$ (SIRUNYAN 21A) and assuming $\kappa_V \leq 1$ and $B_{undetected} \geq 0$.

[11] TUMASYAN 22G combine 13 TeV 101 fb^{-1} results with 8 TeV (KHACHATRYAN 17F) and other 13 TeV (KHACHATRYAN 17F for 2015 and SIRUNYAN 19BO for 2016) for H decaying to invisible final states with VBF topology. The quoted limit on the branching ratio is given for $m_H = 125.38$ GeV and assumes the Standard Model production rates. The branching ratio is obtained to be $0.086^{+0.054}_{-0.052}$. See their Figs. 11 and 12.

[12] TUMASYAN 22G search for $pp \to qqHX$ (VBF) with H decaying to invisible final states using 101 fb^{-1} of data (2017 and 2018). The quoted limit on the branching ratio is given for $m_H = 125.38$ GeV and assumes the Standard Model cross section. See their Figs. 11 and 12.

[13] AAD 21F search for an invisibly decaying Higgs boson with an energetic jet ($p_T > 150$ GeV) and missing transverse momentum (> 200 GeV) in 139 fb^{-1} at $E_{cm} = 13$ TeV. The quoted limit on the branching ratio is given for $m_H = 125$ GeV.

[14] SIRUNYAN 21A search for H decaying to invisible final states associated with a Z decaying $ee/\mu\mu$ using 137 fb^{-1} at 13 TeV. The limit is obtained for $m_H = 125$ GeV and assuming the SM ZH production cross section.

[15] TUMASYAN 21D search for H decaying to invisible final states associated with an energetic jet or a V, $V \to q\bar{q}$ using 101 fb^{-1} at 13 TeV and the result is combined with SIRUNYAN 18S.

[16] AABOUD 19AI search for $pp \to qqHX$ (VBF) with H decaying to invisible final states using 36.1 fb^{-1} of data. The quoted limit on the branching ratio is given for $m_H = 125$ GeV and assumes the Standard Model rates for VBF and gluon-fusion production.

[17] AABOUD 19AL combine results of H decaying to invisible final states with VBF(AABOUD 19AI), ZH, and WH productions (AABOUD 18, AABOUD 18CA), which use 36.1 fb^{-1} of data at 13 TeV. The quoted limit is given for $m_H = 125$ GeV and assumes the Standard Model rates for gluon fusion, VBF, ZH, and WH productions.

[18] AABOUD 19AL combine results of 7, 8 (AAD 15CX), and 13 TeV for H decaying to invisible final states.

[19] SIRUNYAN 19AT perform a combined fit with visible decay using 35.9 fb^{-1} of data at 13 TeV.

[20] SIRUNYAN 19BO search for $pp \to qqHX$ (VBF) with H decaying to invisible final states using 35.9 fb^{-1} of data. The quoted limit on the branching ratio is given for $m_H = 125.09$ GeV and assumes the Standard Model production rates.

[21] SIRUNYAN 19BO combine the VBF channel with results of other 13 TeV analyses: SIRUNYAN 18BV and SIRUNYAN 18S. The quoted limit on the branching ratio is given for $m_H = 125.09$ GeV and assumes the Standard Model production rates.

[22] SIRUNYAN 19BO combine 13 TeV 35.9 fb^{-1} results with 7, 8, 13 TeV (KHACHATRYAN 17F) for H decaying to invisible final states. The quoted limit on the branching ratio is given for $m_H = 125.09$ GeV and assumes the Standard Model production rates. The branching ratio is obtained to be 0.05 ± 0.03 (stat) ± 0.07(syst).

[23] AABOUD 18 search for $pp \to HZX$, $Z \to ee$, $\mu\mu$ with H decaying to invisible final states in 36.1 fb^{-1} at $E_{cm} = 13$ TeV. The quoted limit on the branching ratio is given for $m_H = 125$ GeV and assumes the Standard Model rate for HZ production.

[24] AABOUD 18CA search for H decaying to invisible final states using WH, and ZH productions, where W and Z hadronically decay. The data of 36.1 fb^{-1} at $E_{cm} = 13$ TeV is used. The quoted limit assumes SM production cross sections with combining the contributions from WH, ZH, ggF and VBF production modes.

[25] SIRUNYAN 18BV search for H decaying to invisible final states associated with a Z, $Z \to \ell\ell$ using 35.9 fb^{-1} at 13 TeV.The limit is obtained for $m_H = 125$ GeV and assuming the SM ZH production cross section.

[26] SIRUNYAN 18S search for H decaying to invisible final states associated with an energetic jet or a V, $V \to q\bar{q}$ using 35.9 fb^{-1} at 13 TeV.

[27] AABOUD 17BD search for H decaying to invisible final states with ≥ 1 jet and VBF events using 3.2 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. A cross-section ratio R^{miss} is used in the measurement. The quoted limit is given for $m_H = 125$ GeV.

[28] KHACHATRYAN 17F search for H decaying to invisible final states with gluon fusion, VBF, ZH, and WH productions using 2.3 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV, 19.7 fb^{-1} at 8 TeV, and 5.1 fb^{-1} at 7 TeV. The quoted limit is given for $m_H = 125$ GeV and assumes the Standard Model rates for gluon fusion, VBF, ZH, and WH productions.

[29] AAD 16AF search for $pp \to qqHX$ (VBF) with H decaying to invisible final states in 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The quoted limit on the branching ratio is given for $m_H = 125$ GeV and assumes the Standard Model rates for VBF and gluon-fusion production.

[30] AAD 16AN perform fits to the ATLAS and CMS data at $E_{cm} = 7$ and 8 TeV. The branching fraction of decays into BSM particles that are invisible or into undetected decay modes is measured for $m_0 = 125.09$ GeV.

[31] AAD 15BD search for $pp \to HWX$ and $pp \to HZX$ with W or Z decaying hadronically and H decaying to invisible final states using data at $E_{cm} = 8$ TeV. The quoted limit is given for $m_H = 125$ GeV, assumes the Standard Model rates for the production processes and is based on a combination of the contributions from HW, HZ and the gluon-fusion process.

[32] AAD 15CX search for H decaying to invisible final states with VBF, ZH, and WH productions using 20.3 fb^{-1} at 8 TeV, and 4.7 fb^{-1} at 7 TeV. The quoted limit is given for $m_H = 125.36$ GeV and assumes the Standard Model rates for gluon fusion, VBF, ZH, and WH productions. The upper limit is improved to 0.23 by adding the measured visible decay rates.

[33] AAD 14O search for $pp \to HZX$, $Z \to \ell\ell$, with H decaying to invisible final states in 4.5 fb^{-1} at $E_{cm} = 7$ TeV and 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The quoted limit on the branching ratio is given for $m_H = 125.5$ GeV and assumes the Standard Model rate for HZ production.

[34] CHATRCHYAN 14B search for $pp \to HZX$, $Z \to \ell\ell$ and $Z \to b\bar{b}$, and also $pp \to qqHX$ with H decaying to invisible final states using data at $E_{cm} = 7$ and 8 TeV. The quoted limit on the branching ratio is obtained from a combination of the limits from HZ and qqH. It is given for $m_H = 125$ GeV and assumes the Standard Model rates for the two production processes.

[35] CHATRCHYAN 14B search for $pp \to HZX$ with H decaying to invisible final states and $Z \to \ell\ell$ in 4.9 fb^{-1} at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV, and also with $Z \to b\bar{b}$ in 18.9 fb^{-1} at $E_{cm} = 8$ TeV. The quoted limit on the branching ratio is given for $m_H = 125$ GeV and assumes the Standard Model rate for HZ production.

[36] CHATRCHYAN 14B search for $pp \to qqHX$ (vector boson fusion) with H decaying to invisible final states in 19.5 fb^{-1} at $E_{cm} = 8$ TeV. The quoted limit on the branching ratio is given for $m_H = 125$ GeV and assumes the Standard Model rate for qqH production.

$\Gamma(\gamma\text{invisible})/\Gamma_{\text{total}}$ Γ_{32}/Γ

<0.029	95	[1,2] SIRUNYAN	21L	CMS	VBF, HZ, $H \to \gamma$ + invisible, 13 TeV
• • • We do not use the following data for averages, fits, limits, etc. • • •					
<0.035	95	[1] SIRUNYAN	21L	CMS	VBF, $H \to \gamma$+ invisible, 13 TeV
<0.046	95	[3] SIRUNYAN	19CG	CMS	$pp \to HZ$, $H \to \gamma$+ invisible, $Z \to \ell\ell$, 13 TeV

[1] SIRUNYAN 21L search for H decaying to an invisible final state plus a γ in the VBF production using 130 fb^{-1} data at E_{cm} = 13 TeV. The invisible state is called a dark photon. The quoted limit on the branching ratio is given for m_H = 125 GeV assuming the Standard Model rates.

[2] The result of the VBF production is combined with the $pp \to HZ$ result (SIRUNYAN 19CG).

[3] SIRUNYAN 19CG search for $pp \to HZ$, $Z \to ee$, $\mu\mu$ with H decaying to invisible final states plus a γ in 137 fb^{-1} at E_{cm} = 13 TeV. The quoted limit on the branching ratio is given for m_H = 125 GeV assuming the Standard Model rate for HZ production and is obtained in the context of a theoretical model, where the undetected (invisible) particle is massless.

H SIGNAL STRENGTHS IN DIFFERENT CHANNELS

The H signal strength in a particular final state xx is given by the cross section times branching ratio in this channel normalized to the Standard Model (SM) value, $\sigma \cdot B(H \to xx) / (\sigma \cdot B(H \to xx))_{SM}$, for the specified mass value of H. For the SM predictions, see DITTMAIER 11, DITTMAIER 12, and HEINEMEYER 13A. Results for fiducial and differential cross sections are also listed below.

[1] ATLAS 22 report combined results (see their Extended Data Table 1) using up to 139 fb^{-1} of data at E_{cm} = 13 TeV, assuming m_H = 125.09 GeV. The Higgs production cross-sections, branching fractions and several ratios are found in their Figs. 2 and 3.

[2] CMS 22 report combined results (see their Extended Data Table 2) using 138 fb^{-1} of data at E_{cm} = 13 TeV, assuming m_H = 125.38 GeV. Signal strengths for production modes and decay channels are found in their Fig. 2.

[3] AAD 16AN perform fits to the ATLAS and CMS data at E_{cm} = 7 and 8 TeV. The signal strengths for individual production processes are $1.03^{+0.16}_{-0.14}$ for gluon fusion, $1.18^{+0.25}_{-0.23}$ for vector boson fusion, $0.89^{+0.40}_{-0.38}$ for WH production, $0.79^{+0.38}_{-0.36}$ for ZH production, and $2.3^{+0.7}_{-0.6}$ for $t\overline{t}H$ production.

[4] AAD 16AN: The uncertainties represent statistics, experimental systematics, and added in quadrature theory systematics on the background and on the signal. The quoted signal strengths are given for m_H = 125.09 GeV. In the fit, relative branching ratios and relative production cross sections are fixed to those in the Standard Model.

[5] AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb^{-1} and 9.7 fb^{-1}, respectively, of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_H = 125 GeV.

[6] AAD 20 combine results of up to 79.8 fb^{-1} of data at E_{cm} = 13 TeV, assuming m_H = 125.09 GeV: $\gamma\gamma$, ZZ^*, WW^*, $\tau\tau$, $b\overline{b}$, $\mu\mu$, invisible, and off-shell analyses (see their Table I). The signal strengths for individual production processes are 1.04 ± 0.09 for gluon fusion, $1.21^{+0.24}_{-0.22}$ for vector boson fusion, $1.30^{+0.40}_{-0.38}$ for WH production, $1.05^{+0.31}_{-0.29}$ for ZH production, and $1.21^{+0.26}_{-0.24}$ for $t\overline{t}H+tH$ production (see their Fig. 2 and Table IV). Several results with the simplified template cross section and κ-frameworks are presented: see their Figs. 9–11, Figs 20, 21 and Table VIII for stage-1 simplified template cross sections, their Figs. 12–17 and Tables X–XII for the κ-framework.

[7] SIRUNYAN 19AT combine results of 35.9 fb^{-1} of data at E_{cm} = 13 TeV, assuming m_H = 125.09 GeV. The signal strengths for individual production processes are $1.22^{+0.14}_{-0.12}$ for gluon fusion, $0.73^{+0.30}_{-0.27}$ for vector boson fusion, $2.18^{+0.58}_{-0.55}$ for WH production, $0.87^{+0.44}_{-0.42}$ for ZH production, and $1.18^{+0.30}_{-0.27}$ for $t\overline{t}H$ production. Several results with the simplified template cross section and κ-frameworks are presented: see their Fig. 8 and Table 5 for stage-0 simplified template cross sections, their Figs. 9–18 and Tables 7–11 for the κ-framework.

[8] SIRUNYAN 19BA measure differential cross sections for the Higgs boson transverse momentum, the number of jets, the rapidity of the Higgs boson and the transverse momentum of the leading jet using 35.9 fb^{-1} of data at E_{cm} = 13 TeV with $H \to \gamma\gamma$, $H \to ZZ^*$, and $H \to b\overline{b}$. The total cross section for Higgs boson production is measured to be 61.1 ± 6.0 ± 3.7 pb using $H \to \gamma\gamma$ and $H \to ZZ^*$ channels. Several coupling measurements in the κ-framework are performed.

[9] AAD 16K use up to 4.7 fb^{-1} of pp collisions at E_{cm} = 7 TeV and up to 20.3 fb^{-1} at E_{cm} = 8 TeV. The third uncertainty in the measurement is theory systematics. The signal strengths for individual production modes are $1.23 \pm 0.14^{+0.09+0.16}_{-0.08-0.12}$ for gluon fusion, $1.23^{+0.28+0.13+0.11}_{-0.27-0.12-0.09}$ for vector boson fusion, $0.80^{+0.31}_{-0.30} \pm 0.17^{+0.10}_{-0.05}$ for W/ZH production, and $1.81^{+0.52+0.58+0.31}_{-0.50-0.55-0.12}$ for $t\overline{t}H$ production. The quoted signal strengths are given for m_H = 125.36 GeV.

[10] AAD 15P measure total and differential cross sections of the process $pp \to HX$ at E_{cm} = 8 TeV with 20.3 fb^{-1}. $\gamma\gamma$ and 4ℓ final states are used. $\sigma(pp \to HX)$ = 33.0 ± 5.3 ± 1.6 pb is given. See their Figs. 2 and 3 for data on differential cross sections.

[11] KHACHATRYAN 15AM use up to 5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and up to 19.7 fb^{-1} at E_{cm} = 8 TeV. The third uncertainty in the measurement is theory systematics. Fits to each production mode give the value of $0.85^{+0.19}_{-0.16}$ for gluon fusion, $1.16^{+0.37}_{-0.34}$ for vector boson fusion, $0.92^{+0.38}_{-0.36}$ for WH, ZH production, and $2.90^{+1.08}_{-0.94}$ for $t\overline{t}H$ production.

[12] AAD 13AK use 4.7 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 20.7 fb^{-1} at E_{cm} = 8 TeV. The combined signal strength is based on the $\gamma\gamma$, $ZZ^* \to 4\ell$, and $WW^* \to \ell\nu\ell\nu$ channels. The quoted signal strength is given for m_H = 125.5 GeV. Reported statistical error value modified following private communication with the experiment.

[13] AALTONEN 13L combine all CDF results with 9.45–10.0 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_H = 125 GeV.

[14] ABAZOV 13L combine all D0 results with up to 9.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_H = 125 GeV.

[15] AAD 12AI obtain results based on 4.6–4.8 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 5.8–5.9 fb^{-1} at E_{cm} = 8 TeV. An excess of events over background with a local significance of 5.9 σ is observed at m_H = 126 GeV. The quoted signal strengths are given for m_H = 126 GeV. See also AAD 12DA.

[16] CHATRCHYAN 12N obtain results based on 4.9–5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 5.1–5.3 fb^{-1} at E_{cm} = 8 TeV. An excess of events over background with a local significance of 5.0 σ is observed at about m_H = 125 GeV. The combined signal strength is based on the $\gamma\gamma$, ZZ^*, WW^*, $\tau^+\tau^-$, and $b\overline{b}$ channels. The quoted signal strength is given for m_H = 125.5 GeV. See also CHATRCHYAN 13Y.

[1] CMS 22 report combined results (see their Extended Data Table 2) using up to 138 fb^{-1} of data at E_{cm} = 13 TeV, assuming m_H = 125.38 GeV. See their Fig. 2 right.

[2] AAD 16AN perform fits to the ATLAS and CMS data at E_{cm} = 7 and 8 TeV. The signal strengths for individual production processes are 0.84 ± 0.17 for gluon fusion, 1.2 ± 0.4 for vector boson fusion, $1.6^{+1.2}_{-1.0}$ for WH production, $5.9^{+2.6}_{-2.2}$ for ZH production, and $5.0^{+1.8}_{-1.7}$ for $t\overline{t}H$ production.

[3] AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for m_H = 125.09 GeV.

[4] AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb^{-1} and 9.7 fb^{-1}, respectively, of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_H = 125 GeV.

[5] AAD 23AP measure cross-sections times the $H \to WW^*$ branching fraction in the $H \to WW^* \to e\nu\mu\nu$ channel using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV: $\sigma_{ggF}\times$B($H \to WW^*$) = 12.0 ± 1.4 pb, $\sigma_{VBF}\times$B($H \to WW^*$) = $0.75^{+0.19}_{-0.16}$ pb, and $\sigma_{ggF+VBF}\times$B($H \to WW^*$) = 12.3 ± 1.3 pb. The results are given for m_H = 125.09 GeV. Measured cross sections and ratios to the SM predictions in the reduced stage-1.2 (see their Fig. 5) simplified template cross section framework are shown in their Table VII and Fig. 15.

[6] AAD 23BV measure fiducial total and differential cross sections of VBF process at E_{cm} = 13 TeV with 139 fb^{-1} using $H \to WW^* \to e\nu\mu\nu$. The measured total fiducial cross section is $1.68 \pm 0.33(\text{stat}) \pm 0.23(\text{syst})$ fb in their fiducial region (Table II and Section V). See their Fig. 9 for the comparison with theory predictions. The fiducial differential cross sections are shown in their Figs. 11, 12, and 13. Wilson coefficients in the Warsaw basis at 95% confidence interval are measured; see their Table V and Fig. 16.

[7] TUMASYAN 23W measure Higgs production rates with $H \to WW^*$ at E_{cm} = 13 TeV with 138 fb^{-1} data. The quoted results are given for m_H = 125.38 GeV.

[8] The quoted global signal strength is obtained assuming the relative ratios of different Higgs production modes fixed to the SM values.

[9] The 4 signal strengths for gluon-fusion (ggF), VBF, WH and ZH modes are fit assuming $t\overline{t}H$ and $b\overline{b}H$ fixed to the SM values.

[10] The quoted result is for ggF production mode.

[11] The quoted result is for VBF production mode.

[12] The quoted result is for WH production mode.

[13] The quoted result is for ZH production mode.

[14] Measured cross sections and ratios to the SM predictions in the reduced stage-1.2 (see their Fig. 17) simplified template cross section framework (6 ggF, 4 VBF, and 4 VH) are shown in their Table 18 and Fig. 26.

[15] AAD 22V measure the signal strength for ggF+2jets with 36.1 fb^{-1} data at 13 TeV.

[16] AAD 22V probe the Higgs couplings to longitudinally and transversely polarized W and Z using VBF ($H \to WW^* \to e\nu\mu\nu$ plus two jets) with 36.1 fb^{-1} of data at E_{cm} = 13 TeV. The ratios of the polarization-dependent couplings $g_{HV_LV_L}$ and $g_{HV_TV_T}$ to the Higgs-V coupling predicted by the SM, $a_L = g_{HV_LV_L}/g^{SM}_{HVV}$ and $a_T = g_{HV_TV_T}/g^{SM}_{HVV}$ are measured to be $0.91^{+0.10}_{-0.18}{}^{+0.09}_{-0.17}$ and $1.2 \pm 0.4^{+0.2}_{-0.3}$, respectively, assuming the standard Hgg coupling. These measurements are translated into pseudo-observables of κ_{VV} and ϵ_{VV}: $\kappa_{VV} = 0.91^{+0.10}_{-0.18}{}^{+0.09}_{-0.17}$ and $\epsilon_{VV} = 0.13^{+0.28}_{-0.20}{}^{+0.08}_{-0.10}$, where $\kappa_{VV} = 1$ and $\epsilon_{VV} = 0$ for the SM. See their Tables 9 and 10.

[17] AABOUD 19F measure cross-sections times the $H \to WW^*$ branching fraction in the $H \to WW^* \to e\nu\mu\nu$ channel using 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV: $\sigma_{ggF}\times$B($H \to WW^*$) = $11.4^{+1.2}_{-1.1}{}^{+1.8}_{-1.7}$ pb and $\sigma_{VBF}\times$B($H \to WW^*$) = $0.50^{+0.24}_{-0.22} \pm 0.17$ pb.

[18] AAD 19A use 36.1 fb^{-1} data at 13 TeV. The cross section times branching fraction values are measured to be $0.67^{+0.31}_{-0.27}{}^{+0.18}_{-0.14}$ pb for WH, $H \to WW^*$ and $0.54^{+0.31}_{-0.24}{}^{+0.15}_{-0.24}{}^{-0.07}$ pb for ZH, $H \to WW^*$.

[19] SIRUNYAN 19AT perform a combine fit to 35.9 fb^{-1} of data at E_{cm} = 13 TeV.

[20] SIRUNYAN 19AX measure the signal strengths, cross sections and so on using gluon fusion, VBF and VH production processes with 35.9 fb^{-1} of data. The quoted signal strength is given for m_H = 125.09 GeV. Signal strengths for each production process is found in their Fig. 9. Measured cross sections and ratios to the SM predictions in the stage-0 simplified template cross section framework are shown in their Fig. 10. $\kappa_F = 1.52^{+0.48}_{-0.41}$ and $\kappa_V = 1.10 \pm 0.08$ are obtained (see their Fig. 11 (right)).

[21] AAD 16AO measure fiducial total and differential cross sections of gluon fusion process at E_{cm} = 8 TeV with 20.3 fb^{-1} using $H \to WW^* \to e\nu\mu\nu$. The measured fiducial total cross section is 36.0 ± 9.7 fb in their fiducial region (Table 7). See their Fig. 6 for fiducial differential cross sections. The results are given for m_H = 125 GeV.

[22] AAD 16K use up to 4.7 fb^{-1} of pp collisions at E_{cm} = 7 TeV and up to 20.3 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strength is given for m_H = 125.36 GeV.

[23] AAD 15AA use 4.5 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 20.3 fb^{-1} at E_{cm} = 8 TeV. The signal strength for the gluon fusion and vector boson fusion mode is $1.02 \pm 0.19^{+0.22}_{-0.18}$ and $1.27^{+0.44}_{-0.40}{}^{+0.30}_{-0.21}$, respectively. The quoted signal strengths are given for m_H = 125.36 GeV.

[24] AAD 15AQ use 4.5 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 20.3 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strength is given for m_H = 125.36 GeV.

[25] AAD 15AQ combine their result on W/ZH production with the results of AAD 15AA (gluon fusion and vector boson fusion, slightly updated). The quoted signal strength is given for m_H = 125.36 GeV.

[26] CHATRCHYAN 14G use 4.9 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.4 fb^{-1} at E_{cm} = 8 TeV. The last uncertainty in the measurement is theory systematics. The quoted signal strength is given for m_H = 125.6 GeV.

[27] AAD 13AK use 4.7 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 20.7 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strength is given for m_H = 125.5 GeV. Superseded by AAD 15AA.

[28] AALTONEN 13L combine all CDF results with 9.45–10.0 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_H = 125 GeV.

[29] ABAZOV 13L combine all D0 results with up to 9.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_H = 125 GeV.

[30] AAD 12AI obtain results based on 4.7 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 5.8 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strengths are given for m_H = 126 GeV. See also AAD 12DA.

[31] CHATRCHYAN 12N obtain results based on 4.9 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 5.1 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strength is given for m_H = 125.5 GeV. See also CHATRCHYAN 13Y.

[1] CMS 22 report combined results (see their Extended Data Table 2) using up to 138 fb^{-1} of data at E_{cm} = 13 TeV, assuming m_H = 125.38 GeV. See their Fig. 2 right.

[2] AAD 20AQ perform analyses using $H \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) with data of 139 fb^{-1} at E_{cm} = 13 TeV. Results are given for m_H = 125 GeV.

[3] AAD 20AQ measured the inclusive cross section times branching ratio for $H \to ZZ^*$ decay ($|y(H)| < 2.5$) to be 1.34 ± 0.12 pb (with 1.33 ± 0.08 pb expected in the SM).

[4] AAD 16AN perform fits to the ATLAS and CMS data at E_{cm} = 7 and 8 TeV. The signal strengths for individual production processes are $1.13^{+0.34}_{-0.31}$ for gluon fusion and $0.1^{+1.1}_{-0.6}$ for vector boson fusion.

[5] AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for m_H = 125.09 GeV.

[6] HAYRAPETYAN 23 measure the cross sections for $pp \to H \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) using 138 fb^{-1} at E_{cm} = 13 TeV. They give $\sigma = 2.73 \pm 0.22(\text{stat}) \pm 0.15(\text{syst})$ fb in their fiducial region (see their Section5 and Table 2), where 2.86 ± 0.15 fb is expected in the Standard Model for m_H = 125.38 GeV. 26 differential and 6 double-differential cross sections are given; see their Figs. 6-23 and 24-25.

[7] SIRUNYAN 21AE obtains constraints on anomalous couplings to vector bosons (W, Z, and gluon) and top quark using $H \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) with data of 137 fb^{-1} at E_{cm} = 13 TeV. Their Table 5 and Figs 14–17 show (effective) couplings to gluon and top with combining gluon fusion, $t\overline{t}H$ and tH production channels and the result of $t\overline{t}H$, $H \to \gamma\gamma$ (SIRUNYAN 20AS). Their Tables 6–9 and Figs 18–22 show couplings to W and Z for different assumptions and bases (Higgs and Warsaw).

Gauge & Higgs Boson Particle Listings

H

[8] SIRUNYAN 21S measure cross sections with the $H \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) channel using 137 fb^{-1} data at $E_{cm} = 13$ TeV. Results are given for $m_H = 125.38$ GeV. The signal strengths for individual production processes in their Table 4. Cross sections are given in their Table 6 and Fig. 14, which are based on the simplified template cross section framework (reduced stage-1.2).

[9] AAD 20AQ present several results for the channel $H \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) with the simplified template cross section with κ-frameworks and the effective field theory (EFT) approach; see their Table 8 and Fig. 10 for simplified template cross sections. $\kappa_V = 1.02 \pm 0.06$ and $\kappa_F = 0.88 \pm 0.16$ are obtained, see their Fig. 12 for the κ-framework. See their Tables 9 and 10 and Figs. 16–18 for the EFT-framework.

[10] AAD 20BA measure the cross section for $pp \to H \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) using 139 fb^{-1} at $E_{cm} = 13$ TeV. They give $\sigma \cdot B = 3.28 \pm 0.30 \pm 0.11$ fb in their fiducial region, where 3.41 ± 0.18 fb is expected in the Standard Model for $m_H = 125$ GeV. Various differential cross sections are also given; see their Figs. 19-39. Constraints on Yukawa couplings for bottom and charm quarks are given in their Table 9 and Fig. 41.

[11] AABOUD 19N measure the spectrum of the four-lepton invariant mass $m_{4\ell}$ ($\ell = e$ or μ) using 36.1 fb^{-1} of data at $E_{cm} = 13$ TeV. The quoted signal strength upper limit is obtained from 180 GeV $< m_{4\ell} <$ 1200 GeV.

[12] SIRUNYAN 19AT perform a combine fit to 35.9 fb^{-1} of data at $E_{cm} = 13$ TeV.

[13] AABOUD 18AJ perform analyses using $H \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) with data of 36.1 fb^{-1} at $E_{cm} = 13$ TeV. Results are given for $m_H = 125.09$ GeV. The inclusive cross section times branching ratio for $H \to ZZ^*$ decay ($|\eta(H)| < 2.5$) is measured to be $1.73^{+0.26}_{-0.24}$ pb (with $1.34^{+0.09}_{-0.09}$ pb expected in the SM).

[14] AABOUD 18BP measure an off-shell Higgs boson production using $ZZ \to 4\ell$ and $ZZ \to 2\ell 2\nu$ ($\ell = e,\ \mu$) decay channels with 36.1 fb^{-1} of data at $E_{cm} = 13$ TeV. The quoted signal strength upper limit is obtained from a combination of these two channels, where 220 GeV $< m_{4\ell} <$ 2000 GeV for $ZZ \to 4\ell$ and 250 GeV $< m_T^{ZZ} <$ 2000 GeV for $ZZ \to 2\ell 2\nu$ (m_T^{ZZ} is defined in their Section 5). See their Table 2 for each measurement.

[15] SIRUNYAN 17AV use 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The quoted signal strength, obtained from the analysis of $H \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) decays, is given for $m_H = 125.09$ GeV. The signal strengths for different production modes are given in their Table 3. The fiducial and differential cross sections are shown in their Fig. 10.

[16] AAD 16K use up to 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and up to 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125.36$ GeV.

[17] KHACHATRYAN 16AR use data of 5.1 fb^{-1} at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at 8 TeV. The fiducial cross sections for the production of 4 leptons via $H \to 4\ell$ decays are measured to be $0.56^{+0.67}_{-0.44} {}^{+0.21}_{-0.06}$ fb at 7 TeV and $1.11^{+0.41}_{-0.35} {}^{+0.14}_{-0.10}$ fb at 8 TeV in their fiducial region (Table 2). The differential cross sections at $E_{cm} = 8$ TeV are also shown in Figs. 4 and 5. The results are given for $m_H = 125$ GeV.

[18] AAD 15F use 4.5 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125.36$ GeV. The signal strength for the gluon fusion production mode is $1.66^{+0.45}_{-0.41} {}^{+0.25}_{-0.15}$, while the signal strength for the vector boson fusion production mode is $0.26^{+1.60}_{-0.91} {}^{+0.36}_{-0.23}$.

[19] AAD 14AR measure the cross section for $pp \to H \to ZZ^* \to 4\ell$ ($\ell = e,\ \mu$) using 20.3fb^{-1} at $E_{cm} = 8$ TeV. They give $\sigma \cdot B = 2.11^{+0.53}_{-0.47} \pm 0.08$ fbin their fiducial region, where 1.30 ± 0.13 fb is expected in the Standard Model for m_H= 125.4 GeV. Various differential cross sections are also given; see their Fig. 2.

[20] CHATRCHYAN 14AA use 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125.6$ GeV. The signal strength for the gluon fusion and $t\bar{t}H$ production mode is $0.80^{+0.46}_{-0.36}$, while the signal strength for the vector boson fusion and WH, ZH production mode is $1.7^{+2.2}_{-2.1}$.

[21] AAD 13AK use 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.7 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125.5$ GeV.

[22] CHATRCHYAN 13J obtain results based on $ZZ \to 4\ell$ final states in 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 12.2 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125.8$ GeV. Superseded by CHATRCHYAN 14AA.

[23] AAD 12AI obtain results based on 4.7–4.8 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 5.8 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strengths are given for $m_H = 126$ GeV. See also AAD 12DA.

[24] CHATRCHYAN 12N obtain results based on 4.9–5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 5.1–5.3 fb^{-1} at $E_{cm} = 8$ TeV. An excess of events over background with a local significance of 5.0 σ is observed at about $m_H = 125$ GeV. The quoted signal strengths are given for $m_H = 125.5$ GeV. See also CHATRCHYAN 12BY and CHATRCHYAN 13Y.

[1] AAD 23Y use 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The quoted results are given for $m_H = 125.09$ GeV and $\Gamma_H = 4.07$ MeV. Measured $\sigma \cdot B$ and ratios to the SM predictions for the different production modes are shown in their Table 9 and Fig. 9. Measured cross sections and ratios to the SM predictions in the reduced stage-1.2 (see their Fig. 11) simplified template cross section framework are shown in their Table 10 and Fig. 12. Wilson coefficients in the Warsaw basis (see their Table 11) at 95% CL are measured; see their Table 16 and Fig. 17.

[2] CMS 22 report combined results (see their Extended Data Table 2) using up to 138 fb^{-1} of data at $E_{cm} = 13$ TeV, assuming $m_H = 125.38$ GeV. See their Fig. 2 right.

[3] AAD 16AN perform fits to the ATLAS and CMS data at $E_{cm} = 7$ and 8 TeV. The signal strengths for individual production processes are $1.10^{+0.23}_{-0.22}$ for gluon fusion, 1.3 ± 0.5 for vector boson fusion, $0.5^{+1.3}_{-1.2}$ for WH production, $0.5^{+3.0}_{-2.5}$ for ZH production, and $2.2^{+1.6}_{-1.3}$ for $t\bar{t}H$ production.

[4] AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for $m_H = 125.09$ GeV.

[5] AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb^{-1} and 9.7 fb^{-1}, respectively, of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

[6] TUMASYAN 23Q measure fiducial and differential cross sections at $E_{cm} = 13$ TeV with 137 fb^{-1} data. The quoted results are given for $m_H = 125.38$ GeV. The inclusive fiducial $\sigma \cdot B$ is $73.4^{+5.4}_{-5.3}(\text{stat})^{+2.4}_{-2.2}(\text{syst})$ fb with their defined fiducial region (see their Section 7 and Table 2), where 75.4 ± 4.1 fb is expected in the Standard Model. See their Fig. 8 including other fiducial $\sigma \cdot B$ defined in their Table 3. Differential $\sigma \cdot B$ are shown in their Figs. 10–15. Double-differential $\sigma \cdot B$ are in their Figs. 16 and 17.

[7] AAD 22N measure fiducial and differential cross sections of $pp \to H \to \gamma\gamma$ at $E_{cm} =$ 13 TeV with 139 fb^{-1} data. The quoted results are given for $m_H = 125.09$ GeV. The inclusive fiducial $\sigma \cdot B$ is $67 \pm 5 \pm 4$ fb with their defined fiducial region. Other fiducial $\sigma \cdot B$ are in their Table 3. Differential $\sigma \cdot B$ are shown in their Figs. 8–13, 15, 25–32, 35, 36. Double-differential $\sigma \cdot B$ are in their Figs. 14, 33, 34. Modifications of the b- and c-quark Yukawa couplings to H, κ_b and κ_c at 95% CL are in their Table 6 and Fig. 18. Wilson coefficients at 95% CL are in their Table 7 and Fig. 21.

[8] SIRUNYAN 21O measures cross sections and couplings with the $H \to \gamma\gamma$ channel using 137 fb^{-1} data at $E_{cm} = 13$ TeV. Results are given for $m_H = 125.38$ GeV. The signal strengths for individual production processes are given in their Fig. 16. Cross sections are given in their Tables 12 and 13 and Figs. 18 and 20, which are based on the simplified template cross section framework (reduced stage-1.2). Results in the κ-framework are given in their Fig. 22.

[9] SIRUNYAN 19AT perform a combine fit to 35.9 fb^{-1} of data at $E_{cm} = 13$ TeV.

[10] SIRUNYAN 19L measure fiducial and differential cross sections of the process $pp \to H \to \gamma\gamma$ at $E_{cm} = 13$ TeV with 35.9 fb^{-1}. See their Figs. 4–11.

[11] AABOUD 18BO use 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The signal strengths for the individual production modes are: $0.81^{+0.19}_{-0.18}$ for gluon fusion, $2.0^{+0.6}_{-0.5}$ for vector boson fusion, $0.7^{+0.9}_{-0.8}$ for VH production ($V = W,\ Z$), and 0.5 ± 0.6 for $t\bar{t}H$ and tH production. Other measurements of cross sections and couplings are summarized in their Section 10. The quoted values are given for $m_H = 125.09$ GeV.

[12] SIRUNYAN 18DS use 35.9 fb^{-1} of $pp \to H$ collisions with $H \to \gamma\gamma$ at $E_{cm} = 13$ TeV. The Higgs mass is floated in the measurement of a signal strength. The result is $1.18^{+0.12}_{-0.11}(\text{stat.})^{+0.09}_{-0.07}(\text{syst.})^{+0.07}_{-0.06}(\text{theory})$, which is largely insensitive to the Higgs mass around 125 GeV.

[13] KHACHATRYAN 16G measure fiducial and differential cross sections of the process $pp \to HX$, $H \to \gamma\gamma$ at $E_{cm} = 8$ TeV with 19.7 fb^{-1}. See their Figs. 4–6 and Table 1 for data.

[14] AAD 14BC use 4.5 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The last uncertainty in the measurement is theory systematics. The quoted signal strength is given for $m_H = 125.4$ GeV. The signal strengths for the individual production modes are: 1.32 ± 0.38 for gluon fusion, 0.8 ± 0.7 for vector boson fusion, 1.0 ± 1.6 for WH production, $0.1^{+3.7}_{-0.1}$ for ZH production, and $1.6^{+2.7}_{-1.8}$ for $t\bar{t}H$ production.

[15] AAD 14BJ measure fiducial and differential cross sections of the process $pp \to HX$, $H \to \gamma\gamma$ at $E_{cm} = 8$ TeV with 20.3 fb^{-1}. See their Table 3 and Figs. 3–12 for data.

[16] KHACHATRYAN 14P use 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV. The last uncertainty in the measurement is theory systematics. The quoted signal strength is given for $m_H = 124.7$ GeV. The signal strength for the gluon fusion and $t\bar{t}H$ production mode is $1.13^{+0.37}_{-0.31}$, while the signal strength for the vector boson fusion and WH, ZH production mode is $1.16^{+0.63}_{-0.58}$.

[17] AAD 13AK use 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.7 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125.5$ GeV.

[18] AALTONEN 13L combine all CDF results with 9.45–10.0 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

[19] ABAZOV 13L combine all D0 results with up to 9.7 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

[20] AAD 12AI obtain results based on 4.8 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 5.9 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strengths are given for m_H = 126 GeV. See also AAD 12DA.

[21] CHATRCHYAN 12N obtain results based on 5.1 fb^{-1} of pp collisions at E_{cm}=7 TeV and 5.3 fb^{-1} at E_{cm}=8 TeV. The quoted signal strength is given for m_H=125.5 GeV. See also CHATRCHYAN 13Y.

[1] TUMASYAN 23AH search for VH, $H \to c\overline{c}$ ($V = W,\ Z$) using 138 fb^{-1} of pp collision data at E_{cm} = 13 TeV. The upper limit on $\sigma(pp \to VH)\cdot$B($H \to c\overline{c}$) is 0.94 pb at 95% CL. See their Fig. 4. The quoted values are given for m_H = 125.38 GeV.

[2] TUMASYAN 23AD search for Higgs produced with transverse momenta greater than 450 GeV and decaying to $c\overline{c}$ using 138 fb^{-1} of pp collision data at E_{cm} = 13 TeV.

[3] AAD 22W search for VH, $H \to c\overline{c}$ ($V = W,\ Z$) using 139 fb^{-1} of pp collision data at E_{cm} = 13 TeV. The results are given for m_H = 125 GeV.

[4] The analysis of VH, $H \to c\overline{c}$ is combined with VH, $H \to b\overline{b}$ (AAD 21AB). The ratio $|\kappa_c/\kappa_b|$ is constrained to be less than 4.5 at 95% CL. See their Fig. 7.

[5] The constraint on the charm Yukawa coupling modifier κ_c is measured to be $|\kappa_c|$ <8.5 at 95% CL. See their Fig. 4.

[6] SIRUNYAN 20AE use 35.9 fb^{-1} at of pp collisions at E_{cm} = 13 TeV. The measured best fit value of $\sigma(pp \to VH)\cdot$B($H \to c\overline{c}$) is $2.40^{+1.12+0.65}_{-1.11-0.61}$ pb (equivalent to < 4.5 pb at 95% CL upper limit, i.e. 70 times the standard model), where V is $W \to \ell\nu$, $Z \to \ell\ell$, or $Z \to \nu\nu$ ($\ell = e,\ \mu$). The quoted values are given for m_H = 125 GeV.

[7] AABOUD 18M use 36.1 fb^{-1} at of pp collisions at E_{cm} = 13 TeV. The upper limit on $\sigma(pp \to ZH)\cdot$B($H \to c\overline{c}$) is 2.7 pb at 95% CL. This corresponds to 110 times the standard model. The quoted values are given for m_H = 125 GeV.

[1] CMS 22 report combined results (see their Extended Data Table 2) using up to 138 fb^{-1} of data at E_{cm} = 13 TeV, assuming m_H = 125.38 GeV. See their Fig. 2 right.

[2] AAD 21AB search for VH, $H \to b\overline{b}$ ($V = W,\ Z$) using 139 fb^{-1} of pp collision data at E_{cm} = 13 TeV. The results are given for m_H = 125 GeV. Cross sections are given in their Table 13 and Fig. 7, which are based on the simplified template cross section framework (reduced stage-1.2). Wilson coefficients of the Warsaw-basis operators are given in their Fig. 9.

[3] AAD 21AJ present measurements of $H \to b\overline{b}$ in the VBF production mode. The inclusive VBF cross sections with and without the branching ratio of $H \to b\overline{b}$ are 2.07 ± $0.70^{+0.46}_{-0.37}$ fb and 3.56 ± $1.21^{+0.80}_{-0.64}$ fb, respectively. The latter is obtained assuming the SM value of B($H \to b\overline{b}$) = 0.5809 and m_H = 125 GeV.

[4] AAD 16AN perform fits to the ATLAS and CMS data at E_{cm} = 7 and 8 TeV. The signal strengths for individual production processes are 1.0 ± 0.5 for WH production, 0.4 ± 0.4 for ZH production, and 1.1 ± 1.0 for $t\overline{t}H$ production.

[5] AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for m_H = 125.09 GeV.

[6] AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb^{-1} and 9.7 fb^{-1}, respectively, of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_H = 125 GeV.

[7] AAD 22X measure cross sections using a boosted $H \to b\overline{b}$ with large-radius jets. The data is 136 fb^{-1} of pp collisions at E_{cm} = 13 TeV. All the results are given for m_H = 125 GeV. The inclusive signal strength is given using data with a H candidate jet p_T >250 GeV. The fiducial H production cross section ($p_T(H)$>450 GeV and |y(H)| <2) is <115 fb (95% CL) and the upper limits for other four different p_T regions are shown in their Fig 12. The measured fiducial H production cross section ($p_T(H)$>1 TeV) is 2.3 ± 3.9(stat)±1.3(syst)±0.5(theory) fb.

[8] AAD 21H present measurements of $H \to b\overline{b}$ with a boosted vector boson (p_T > 250 GeV) using 139 fb^{-1} of pp collision data at E_{cm} = 13 TeV. Cross sections are given in their Table 6 and Fig. 4, which are based on the simplified template cross section framework (reduced stage-1.2). Wilson coefficients of the Warsaw-basis operators are given in their Fig. 5.

[9] AAD 21M search for VBF+γ, $H \to b\overline{b}$ using 132 fb^{-1} of pp collision data at E_{cm} = 13 TeV.

[10] SIRUNYAN 20BL search for boosted $H \to b\overline{b}$ (a H candidate jet p_T >450 GeV) using 137 fb^{-1} of pp collision data at E_{cm} = 13 TeV. The quoted signal strength corresponds to a significance of 2.5 standard deviations and is given for m_H = 125 GeV. A differential fiducial cross section as a function of Higgs boson p_T for ggF is shown in their Fig. 7, assuming the other production modes occur at the expected SM rates. The reported value is $3.7 \pm 1.2^{+0.8+0.8}_{-0.7-0.5}$ where the last uncertainty comes from theoretical modeling. We have combined the systematic uncertainties in quadrature.

[11] AABOUD 19U measure cross sections of $pp \to VH$, $H \to b\overline{b}$ production as a function of the gauge boson transverse momentum using data of 79.8 fb^{-1}. The kinematic fiducial volumes used is based on the simplified template cross section framework (reduced stage-1). See their Table 3 and Fig. 3.

[12] SIRUNYAN 19AT perform a combine fit to 35.9 fb^{-1} of data at E_{cm} = 13 TeV.

[13] AABOUD 18BN search for VH, $H \to b\overline{b}$ ($V = W,\ Z$) using 79.8 fb^{-1} of pp collision data at E_{cm} = 13 TeV. The quoted signal strength corresponds to a significance of 4.9 standard deviations and is given for m_H = 125 GeV.

[14] AABOUD 18BN combine results of 79.8 fb^{-1} at E_{cm} = 13 TeV with results of VH at E_{cm} = 7 and 8 TeV.

[15] AABOUD 18BN combine results of VH at E_{cm} = 7, 8 and 13 TeV with results of VBF (+gluon fusion) and $t\overline{t}H$ at E_{cm} = 7, 8, and 13 TeV to perform a search for the $H \to b\overline{b}$ decay. The quoted signal strength assumes a SM production strength and corresponds to a significance of 5.4 standard deviations.

[16] AABOUD 18BQ search for $H \to b\overline{b}$ produced through vector-boson fusion (VBF) and VBF+γ with 30.6 fb^{-1} pp collision data at E_{cm} = 13 TeV. The quoted signal strength is given for m_H = 125 GeV.

[17] The signal strength is measured including all production modes (VBF, ggF, VH, $t\overline{t}H$).

[18] The signal strength is measured for VBF-only and others (ggF, VH, $t\overline{t}H$) are constrained to Standard Model expectations with uncertainties described in their Section VIII B.

[19] AALTONEN 18C use 5.4 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The upper limit at 95% CL on $p\overline{p} \to H \to b\overline{b}$ is 33 times the SM predicion, which corresponds to a cross section of 40.6 pb.

[20] SIRUNYAN 18AE use 35.9 fb^{-1} of pp collision data at E_{cm} = 13 TeV. The quoted signal strength corresponds to 3.3 standard deviations and is given for m_H = 125.09 GeV.

[21] SIRUNYAN 18AE combine the result of 35.9 fb^{-1} at E_{cm} = 13 TeV with the results obtained from data of up to 5.1 fb^{-1} at E_{cm} = 7 TeV and up to 18.9 fb^{-1} at E_{cm} = 8 TeV (CHATRCHYAN 14AI and KHACHATRYAN 15Z). The quoted signal strength corresponds to 3.8 standard deviations and is given for m_H = 125.09 GeV.

[22] SIRUNYAN 18DB search for VH, $H \to b\overline{b}$ ($V = W$, Z) using 77.2 fb^{-1} of pp collision data at E_{cm} = 13 TeV. The quoted signal strength corresponds to a significance of 4.4 standard deviations and is given for m_H = 125.09 GeV.

[23] SIRUNYAN 18DB combine the result of 77.2 fb^{-1} at E_{cm} = 13 TeV with the results obtained from data of up to 5.1 fb^{-1} at E_{cm} = 7 TeV and up to 18.9 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strength corresponds to a significance of 4.8 standard deviations and is given for m_H = 125.09 GeV.

[24] SIRUNYAN 18DB combine results of 77.2 fb^{-1} at E_{cm} = 13 TeV with results of gluon fusion (ggF), VBF and $t\overline{t}H$ at E_{cm} = 7 TeV, 8 TeV and 13 TeV to perform a search for the $H \to b\overline{b}$ decay. The quoted signal strength assumes a SM production strength and corresponds to a significance of 5.6 standard deviations and is given for m_H = 125.09 GeV.

[25] SIRUNYAN 18E use 35.9 fb^{-1} at E_{cm} = 13 TeV. The quoted signal strength is given for m_H = 125 GeV. They measure $\sigma \cdot B$ for gluon fusion production of $H \to b\overline{b}$ with p_T >450 GeV, $|\eta|$ <2.5 to be $74 \pm 48^{+17}_{-10}$ fb.

[26] AABOUD 17BA use 36.1 fb^{-1} at E_{cm} = 13 TeV. The quoted signal strength is given for m_H = 125 GeV. They give $\sigma(\text{W H}) \cdot B(H \to b\overline{b}) = 1.08^{+0.54}_{-0.47}$ pb and $\sigma(\text{Z H}) \cdot B(H \to b\overline{b}) = 0.57^{+0.26}_{-0.23}$ pb.

[27] AABOUD 17BA combine 7, 8 and 13 TeV analyses. The quoted signal strength is given for m_H = 125 GeV.

[28] AABOUD 16X search for vector-boson fusion production of H decaying to $b\overline{b}$ in 20.2 fb^{-1} of pp collisions at E_{cm} = 8 TeV. The quoted signal strength is given for m_H = 125 GeV.

[29] AAD 16K use up to 4.7 fb^{-1} of pp collisions at E_{cm} = 7 TeV and up to 20.3 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strength is given for m_H = 125.36 GeV.

[30] AAD 15G use 4.7 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 20.3 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strength is given for m_H = 125.36 GeV.

[31] KHACHATRYAN 15Z search for vector-boson fusion production of H decaying to $b\overline{b}$ in up to 19.8 fb^{-1} of pp collisions at E_{cm} = 8 TeV. The quoted signal strength is given for m_H = 125 GeV.

[32] KHACHATRYAN 15Z combined vector boson fusion, WH, ZH production, and $t\overline{t}H$ production results. The quoted signal strength is given for m_H = 125 GeV.

[33] CHATRCHYAN 14AI use up to 5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and up to 18.9 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strength is given for m_H = 125 GeV. See also CHATRCHYAN 14AJ.

[34] AALTONEN 13L combine all CDF results with 9.45–10.0 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_H = 125 GeV.

[35] ABAZOV 13L combine all D0 results with up to 9.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_H = 125 GeV.

[36] AAD 12AI obtain results based on 4.6–4.8 fb^{-1} of pp collisions at E_{cm} = 7 TeV. The quoted signal strengths are given in their Fig. 10 for m_H = 126 GeV. See also Fig. 13 of AAD 12DA.

[37] AALTONEN 12T combine AALTONEN 12Q, AALTONEN 12R, AALTONEN 12S, ABAZOV 12O, ABAZOV 12P, and ABAZOV 12K. An excess of events over background is observed which is most significant in the region m_H = 120–135 GeV, with a local significance of up to 3.3 σ. The local significance at m_H = 125 GeV is 2.8 σ, which corresponds to $(\sigma(HW) + \sigma(HZ)) \cdot \text{B}(H \to b\overline{b}) = (0.23^{+0.09}_{-0.08})$ pb, compared to the Standard Model expectation at m_H = 125 GeV of 0.12 ± 0.01 pb. Superseded by AALTONEN 13M.

[38] CHATRCHYAN 12N obtain results based on 5.0 fb^{-1} of pp collisions at E_{cm}=7 TeV and 5.1 fb^{-1} at E_{cm}=8 TeV. The quoted signal strength is given for m_H=125.5 GeV. See also CHATRCHYAN 13Y.

[1] CMS 22 report combined results (see their Extended Data Table 2) using up to 138 fb^{-1} of data at E_{cm} = 13 TeV, assuming m_H = 125.38 GeV. See their Fig. 2 right.

[2] AAD 21 search for $H \to \mu^+\mu^-$ using 139 fb^{-1} of pp collision data at E_{cm} = 13 TeV. The quoted signal strength corresponds to a significance of 2.0 standard deviations and is given for m_H = 125.09 GeV. The upper limit on the cross section times branching fraction is 2.2 times the SM prediction at 95% CL, which corresponds to the branching fraction upper limit of 4.7×10^{-4} (assuming SM production cross sections).

[3] SIRUNYAN 21 search for $H \to \mu^+\mu^-$ using 137 fb^{-1} of pp collision data at E_{cm} = 13 TeV. The quoted signal strength corresponds to a significance of 3.0 standard deviations and is given for m_H = 125.38 GeV.

[4] SIRUNYAN 19AT perform a combine fit to 35.9 fb^{-1} of data at E_{cm} = 13 TeV.

[5] SIRUNYAN 19E search for $H \to \mu^+\mu^-$ using 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV and combine with results of 7 TeV (5.0 fb^{-1}) and 8 TeV (19.7 fb^{-1}). The upper limit at 95% CL on the signal strength is 2.9, which corresponds to the SM Higgs boson branching fraction to a muon pair of 6.4×10^{-4}.

[6] AABOUD 17Y use 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV, 20.3 fb^{-1} at 8 TeV and 4.5 fb^{-1} at 7 TeV. The quoted signal strength is given for m_H = 125 GeV.

[7] AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for m_H = 125.09 GeV.

[8] KHACHATRYAN 15H use 5.0 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.7 fb^{-1} at 8 TeV. The quoted signal strength is given for m_H = 125 GeV.

[9] AAD 14AS search for $H \to \mu^+\mu^-$ in 4.5 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 20.3 fb^{-1} at E_{cm} = 8 TeV. The quoted signal strength is given for m_H = 125.5 GeV.

[1] CMS 22 report combined results (see their Extended Data Table 2) using up to 138 fb^{-1} of data at E_{cm} = 13 TeV, assuming m_H = 125.38 GeV. See their Fig. 2 right.

[2] AABOUD 19AQ use 36.1 fb^{-1} of data. The first, second and third quoted errors are statistical, experimental systematic and theory systematic uncertainties, respectively. The quoted signal strength is given for m_H = 125 GeV and corresponds to 4.4 standard deviations. Combining with 7 TeV and 8 TeV results (AAD 15AH), the observed significance is 6.4 standard deviations. The cross sections in the $H \to \tau\tau$ decay channel (m_H = 125 GeV) are measured to $3.77^{+0.60}_{-0.59}$ (stat) $^{+0.87}_{-0.74}$ (syst) pb for the inclusive, $0.28 \pm 0.09^{+0.11}_{-0.09}$ pb for VBF, and $3.1 \pm 1.0^{+1.6}_{-1.3}$ pb for gluon-fusion production. See their Table XI for the cross sections in the framework of simplified template cross sections.

[3] AAD 16AN perform fits to the ATLAS and CMS data at E_{cm} = 7 and 8 TeV. The signal strengths for individual production processes are 1.0 ± 0.6 for gluon fusion, 1.3 ± 0.4 for vector boson fusion, -1.4 ± 1.4 for WH production, $2.2^{+2.2}_{-1.8}$ for ZH production, and $-1.9^{+3.7}_{-3.3}$ for $t\overline{t}H$ production.

[4] AAD 16AN: In the fit, relative production cross sections are fixed to those in the Standard Model. The quoted signal strength is given for m_H = 125.09 GeV.

[5] AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations with up to 10.0 fb^{-1} and 9.7 fb^{-1}, respectively, of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The quoted signal strength is given for m_H = 125 GeV.

[6] TUMASYAN 23Y measure Higgs production with $pp \to H \to \tau\tau$ at E_{cm} = 13 TeV with 138 fb^{-1} data. The quoted results are given for m_H = 125.38 GeV.

[7] The inclusive $\sigma \cdot B$ is 2800^{+356}_{-335} fb (see their Figs. 10 and 14). See their Fig. 15 for the 68 % and 95 % CL contours in the $\kappa_V - \kappa_F$ plane.

[8] The quoted result is for the stage-0 simplified template cross section (STXS) and the $\sigma_{ggF} \cdot B$ is 2030^{+598}_{-555} fb (see their Figs. 10 and 14). Measured cross sections and ratios to the SM predictions in the reduced stage-1.2 STXS (see their Fig. 1) are shown in their Table 9 and Figs. 12 and 14.

[9] The quoted result is for the stage-0 STXS and the $\sigma_{VBF} \cdot B$ is $267^{+53.9}_{-52.6}$ fb (see their Figs. 10 and 14). Measured cross sections and ratios to the SM predictions in the reduced stage-1.2 STXS (see their Fig. 2) are shown in their Table 9 and Figs. 12, 14.

[10] The quoted result is for the stage-0 STXS and the $\sigma_{VH} \cdot B$ is $79.0^{+20.5}_{-18.6}$ fb (see their Figs. 10 and 14). Measured cross sections and ratios to the SM predictions in the reduced stage-1.2 STXS (see their Fig. 3) are shown in their Table 9 and Figs. 12, 14.

[11] AAD 22Q measure cross sections of $pp \to H \to \tau\tau$ at $E_{cm} = 13$ TeV with 139 fb^{-1} data. The quoted results are given for $m_H = 125.09$ GeV and $|y(H)| < 2.5$ is required. The inclusive fiducial $\sigma \cdot B$ is $2.94 \pm 0.21^{+0.37}_{-0.32}$ pb. The fiducial $\sigma \cdot B$ for the four dominant production modes are $2.65 \pm 0.41^{+0.91}_{-0.67}$ pb for ggF, $0.197 \pm 0.028^{+0.032}_{-0.026}$ pb for VBF, $0.115 \pm 0.058^{+0.042}_{-0.040}$ pb for VH, $0.033 \pm 0.031^{+0.022}_{-0.017}$ pb for $t\bar{t}H$. The cross sections using simplified template cross section framework (STXS) are given in their Fig. 14(a) and Table 15. The STXS bins (a reduced stage 1.2) are defined in their Fig. 1.

[12] TUMASYAN 22AJ measure cross sections with $pp \to H \to \tau\tau$ at $E_{cm} = 13$ TeV with 138 fb^{-1} data. The fiducial inclusive $\sigma \cdot B$ is 426 ± 102 fb while 408 ± 27 fb is expected in the Standard Mode for $m_H = 125.38$ GeV. Three differential cross sections are given; see their Fig. 1.

[13] SIRUNYAN 19AF use 35.9 fb^{-1} of data. The quoted signal strength is given for $m_H = 125$ GeV and corresponds to 2.3 standard deviations.

[14] SIRUNYAN 19AF use 35.9 fb^{-1} of data. HW/Z channels are added with a few updates on gluon fusion and vector boson fusion with respect to SIRUNYAN 18Y. The quoted signal strength is given for $m_H = 125$ GeV and corresponds to 5.5 standard deviations. The signal strengths for the individual production modes are: $1.12^{+0.53}_{-0.50}$ for gluon fusion, $1.13^{+0.45}_{-0.42}$ for vector boson fusion, $3.39^{+1.68}_{-1.54}$ for WH and $1.23^{+1.62}_{-1.35}$ for ZH. See their Fig. 7 for other couplings (κ_V, κ_f).

[15] SIRUNYAN 19AT perform a combine fit to 35.9 fb^{-1} of data at $E_{cm} = 13$ TeV. This combination is based on SIRUNYAN 18Y.

[16] SIRUNYAN 18Y use 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The quoted signal strength is given for $m_H = 125.09$ GeV and corresponds to 4.9 standard deviations.

[17] SIRUNYAN 18Y combine the result of 35.9 fb^{-1} at $E_{cm} = 13$ TeV with the results obtained from data of 4.9 fb^{-1} at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV (KHACHATRYAN 15AM). The quoted signal strength is given for $m_H = 125.09$ GeV and corresponds to 5.9 standard deviations.

[18] AAD 16AC measure the signal strength with $pp \to HW/ZX$ processes using 20.3 fb^{-1} of $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

[19] AAD 16K use up to 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and up to 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125.36$ GeV.

[20] AAD 15AH use 4.5 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The third uncertainty in the measurement is theory systematics. The signal strength for the gluon fusion mode is $2.0 \pm 0.8^{+1.2}_{-0.8} \pm 0.3$ and that for vector boson fusion and W/ZH production modes is $1.24^{+0.49}_{-0.45}{}^{+0.31}_{-0.29} \pm 0.08$. The quoted signal strength is given for $m_H = 125.36$ GeV.

[21] CHATRCHYAN 14K use 4.9 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125$ GeV. See also CHATRCHYAN 14AJ.

[22] AALTONEN 13L combine all CDF results with 9.45–10.0 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

[23] ABAZOV 13L combine all D0 results with up to 9.7 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

[24] AAD 12AI obtain results based on 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV. The quoted signal strengths are given in their Fig. 10 for $m_H = 126$ GeV. See also Fig. 13 of AAD 12DA.

[25] CHATRCHYAN 12N obtain results based on 4.9 fb^{-1} of pp collisions at E_{cm}=7 TeV and 5.1 fb^{-1} at E_{cm}=8 TeV. The quoted signal strength is given for m_H=125.5 GeV. See also CHATRCHYAN 13Y .

[1] AAD 24D report combined results of ATLAS (AAD 20AG) and CMS (TUMASYAN 23F). The reported signal strength corresponds to a significance of 3.4 σ.

[2] TUMASYAN 23F search for $H \to Z\gamma$, $Z \to ee$, $\mu\mu$ in 138 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV, assuming $m_H = 125.38$ GeV. $\sigma(pp \to H) \cdot B(H \to Z\gamma)$ is measured to be 0.21 ± 0.08 pb. The ratio of branching fractions $B(H \to Z\gamma)/B(H \to \gamma\gamma)$ is measured to be $1.5^{+0.7}_{-0.6}$.

[3] CMS 22 report combined results (see their Extended Data Table 2) using up to 138 fb^{-1} of data at $E_{cm} = 13$ TeV, assuming $m_H = 125.38$ GeV. See their Fig. 2 right.

[4] AAD 20AG search for $H \to Z\gamma$, $Z \to ee$, $\mu\mu$ in 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The signal strength is $2.0 \pm 0.9^{+0.4}_{-0.3}$ at $m_H = 125.09$ GeV, which corresponds to a significance of 2.2 σ. The upper limit of $\sigma(pp \to H) \cdot B(H \to Z\gamma)$ is 305 fb at 95% CL.

[5] SIRUNYAN 18DQ search for $H \to Z\gamma$, $Z \to ee$, $\mu\mu$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The quoted signal strength (see their Figs. 6 and 7) is given for $m_H = 125$ GeV.

[6] AABOUD 17AW search for $H \to Z\gamma$, $Z \to ee$, $\mu\mu$ in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The quoted signal strength is given for $m_H = 125.09$ GeV. The upper limit on the branching ratio of $H \to Z\gamma$ is 1.0% at 95% CL assuming the SM Higgs boson production.

[7] AAD 14J search for $H \to Z\gamma \to \ell\ell\gamma$ in 4.5 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125.5$ GeV.

[8] CHATRCHYAN 13BK search for $H \to Z\gamma \to \ell\ell\gamma$ in 5.0 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.6 fb^{-1} at $E_{cm} = 8$ TeV. A limit on cross section times branching ratio which corresponds to (4–25) times the expected Standard Model cross section is given in the range $m_H = 120$–160 GeV at 95% CL. The quoted limit is given for $m_H = 125$ GeV, where 10 is expected for no signal.

$\gamma^*\gamma$ Final State

VALUE	CL%	DOCUMENT ID		TECN	COMMENT
$1.5 \pm 0.5^{+0.2}_{-0.1}$		[1] AAD	21I	ATLS	pp, 13 TeV, $H \to \ell\ell\gamma$, 139 fb^{-1}

[1] AAD 21I search for $H \to \ell\ell\gamma$ ($\ell = e$, μ) in 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The mass of dilepton $m_{\ell\ell}$ is smaller than 30 GeV. This region is dominated by the decay through γ^*. The quoted signal strength corresponds to a significance of 3.2 standard deviations and is given for $m_H = 125.09$ GeV. The cross section times the branching ratio of $H \to \ell\ell\gamma$ for $m_{\ell\ell} < 30$ GeV is measured to be $8.7 \pm 2.7^{+0.7}_{-0.6}$ fb.

[2] SIRUNYAN 18DQ search for $H \to \gamma^*\gamma$, $\gamma^* \to \mu\mu$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The mass of γ^* is smaller than 50 GeV except in J/ψ and Υ mass regions. The quoted signal strength (see their Figs. 6 and 7) is given for $m_H = 125$ GeV.

[3] KHACHATRYAN 16B search for $H \to \gamma^*\gamma \to e^+e^-\gamma$ and $\mu^+\mu^-\gamma$ (with $m(e^+e^-) < 3.5$ GeV and $m(\mu^+\mu^-) < 20$ GeV) in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 6 for limits on individual channels.

[1] AAD 23BC measure the production of four top quarks with same-sign and multilepton final states with 140 fb^{-1} pp collision data at E_{cm} = 13 TeV. The results constraint the ratio of the top quark Yukawa coupling y_t to its Standard Model value, yielding $|y_t/y_t^{SM}| < 1.8$ at 95% CL. See their Fig. 8 as a function of κ_t and *CP*-mixing angle.
[2] AAD 23Y constrain κ_t from Higgs production rates with $H \to \gamma\gamma$ with 139 fb^{-1} pp collision data at E_{cm} = 13 TeV. The quoted result is obtained assuming the SM loop structure in $gg \to H$ and $H \to \gamma\gamma$. See their Fig. 14.
[3] AAD 23Y constrain κ_t from Higgs production rates with $H \to \gamma\gamma$ with 139 fb^{-1} pp collision data at E_{cm} = 13 TeV. The quoted result is obtained assuming effective couplings κ_{gluon} and κ_γ for $gg \to H$ and $H \to \gamma\gamma$, respectively. See their Fig. 14.
[4] TUMASYAN 23P constrain κ_t from $t\bar{t}H$ and tH decaying $H \to WW^*$ and $H \to \tau\tau$ (multilepton decay mode) with 138 fb^{-1} pp collision data at E_{cm} = 13 TeV. The κ_t is obtained by fixing $\tilde{\kappa}_t = 0$ and other couplings (κ_V etc.) to the SM values. See their Fig. 9 for 2-dim contours and Table 6.
[5] The quoted result is obtained by combining with other $t\bar{t}H$ decaying $H \to \gamma\gamma$ (SIRUNYAN 20AS) and $H \to 4\ell$ (SIRUNYAN 21AE) and $\tilde{\kappa}_t = 0$. See their Fig. 12 for 2-dim contours and Table 7.
[6] ATLAS 22 report combined results (see their Extended Data Table 1) using up to 139 fb^{-1} of data at E_{cm} = 13 TeV, assuming m_H = 125.09 GeV.
[7] All modifiers(κ) > 0, and $\kappa_c = \kappa_t$ ($B_{inv} = B_{undetected} = 0$) are assumed. Only SM particles assume to contribute to the loop-induced processes.See their Fig. 5, which shows both $\kappa_c = \kappa_t$ andκ_c floating.
[8] $B_{inv} = B_{undetected} = 0$ is assumed. Coupling strength modifiers including effective photon, $Z\gamma$ and gluon are measured. See their Fig. 6.
[9] B_{inv} floating, $B_{undetected} \geq 0$, and $\kappa_V \leq 1$ are assumed. Coupling strength modifiers including effective photon, $Z\gamma$ and gluon are measured. See their Fig. 6.
[10] CMS 22 report combined results (see their Extended Data Table 2) using up to 138 fb^{-1} of data at E_{cm} = 13 TeV, assuming m_H = 125.38 GeV.
[11] Only SM particles assume to contribute to the loop-induced processes. See their Fig. 3 right.
[12] Coupling strength modifiers including effective photon, $Z\gamma$ and gluon are measured. See their Fig. 4 left.
[13] SIRUNYAN 21R constrain the ratio of the top quark Yukawa coupling y_t to its Standard Model value from $t\bar{t}H$ and tH production rates using 137 fb^{-1} pp collision data at E_{cm} = 13 TeV. Assuming a SM Higgs couplings to τ's, the joint interval $-0.9 < \kappa_t(=y_t/y_t^{SM}) < -0.7$ and $0.7 < \kappa_t < 1.1$ is obtained at 95% CL (see their Fig. 17).
[14] SIRUNYAN 20C search for the production of four top quarks with same-sign and multilepton final states with 137 fb^{-1} pp collision data at E_{cm} = 13 TeV. The results constraint the ratio of the top quark Yukawa coupling y_t to its Standard Model value by comparing to the central value of a theoretical prediction (see their Refs. [1-2]), yielding $|y_t/y_t^{SM}| < 1.7$ at 95% CL. See their Fig. 5.
[15] SIRUNYAN 19BY measure the top quark Yukawa coupling from $t\bar{t}$ kinematic distributions, the invariant mass of the top quark pair and the rapidity difference between t and $\bar{t}$, in the ℓ+jets final state with 35.8 fb^{-1} pp collision data at E_{cm} = 13 TeV. The results constraint the ratio of the top quark Yukawa coupling to its the Standard Model to be $1.07^{+0.34}_{-0.43}$ with an upper limit of 1.67 at 95% CL (see their Table III).
[16] SIRUNYAN 18BU search for the production of four top quarks with same-sign and multilepton final states with 35.9 fb^{-1} pp collision data at E_{cm} = 13 TeV. The results constraint the ratio of the top quark Yukawa coupling y_t to its the Standard Model by comparing to the central value of a theoretical prediction (see their Ref. [16]), yielding $|y_t/y_t^{SM}| < 2.1$ at 95% CL.

[1] SIRUNYAN 21R search for $t\overline{t}H$ in final states with electrons, muons and hadronically decaying τ leptons ($H \to WW^*$, ZZ^*, $\tau\tau$) with 137 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. The quoted signal strength corresponds to a significance of 4.7 standard deviations and is given for $m_H = 125$ GeV.

[2] AABOUD 18AC combine results of $t\overline{t}H$, $H \to \tau\tau$, $WW^*(\to \ell\nu\ell\nu, \ell\nu q\overline{q})$, $ZZ^*(\to \ell\ell\nu\nu, \ell\ell q\overline{q})$ with results of $t\overline{t}H$, $H \to b\overline{b}$ (AABOUD 18T), $\gamma\gamma$ (AABOUD 18BO), $ZZ^*(\to 4\ell)$ (AABOUD 18AJ) in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The quoted signal strength is given for $m_H = 125$ GeV. See their Table 14.

[3] AAD 16AN: In the fit, relative branching ratios are fixed to those in the Standard Model. The quoted signal strength is given for $m_H = 125.09$ GeV.

[4] TUMASYAN 23AI measure boosted $H \to b\overline{b}$ ($p_T > 200$ GeV) in $t\overline{t}H$ production using 138 fb^{-1} of data at $E_{cm} = 13$ TeV. The differential cross section for the Higgs p_T is shown in their Fig. 8 and Table V. Limits on eight Wilson coefficients at 68% and 95% CL are shown in their Fig. 10 and Table VI.

[5] AAD 22M measure $H \to b\overline{b}$ in $t\overline{t}H$ production using 139 fb^{-1} of data at $E_{cm} = 13$ TeV. See their Fig. 14. The signal strengths and 95% CL cross section upper limits with simplified template cross section bins are given in their Figs. 18 and 19, respectively.

[6] AAD 20Z measure $\sigma_{t\overline{t}H} \cdot B(H \to \gamma\gamma)$ to be $1.64^{+0.38}_{-0.36}{}^{+0.17}_{-0.14}$ fb in 139 fb^{-1} of data at $E_{cm} = 13$ TeV.

[7] SIRUNYAN 20AS measure $\sigma_{t\overline{t}H} \cdot B(H \to \gamma\gamma)$ to be $1.56^{+0.34}_{-0.32}$ fb in 137 fb^{-1} of data at $E_{cm} = 13$ TeV.

[8] SIRUNYAN 19R search for $t\overline{t}H$ production with H decaying to $b\overline{b}$ in 35.9 fb^{-1} of data at $E_{cm} = 13$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

[9] AABOUD 18AC search for $t\overline{t}H$ production with H decaying to $\tau\tau$, $WW^*(\to \ell\nu\ell\nu, \ell\nu q\overline{q})$, $ZZ^*(\to \ell\ell\nu\nu, \ell\ell q\overline{q})$ in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The quoted signal strength is given for $m_H = 125$ GeV. See their Table 13 and Fig. 13.

[10] AABOUD 18BK use 79.8 fb^{-1} data for $t\overline{t}H$ production with $H \to \gamma\gamma$ and $ZZ^* \to 4\ell$ ($\ell = e, \mu$) and 36.1 fb^{-1} for other decay channels at $E_{cm} = 13$ TeV. A significance of 5.8 standard deviations is observed for $m_H = 125.09$ GeV and its signal strength without the uncertainty of the $t\overline{t}H$ cross section is $1.32^{+0.28}_{-0.26}$. Combining with results of 7 and 8 TeV (AAD 16K), the significance is 6.3 standard deviations. Assuming Standard Model branching fractions, the total $t\overline{t}H$ production cross section at 13 TeV is measured to be $670 \pm 90^{+110}_{-100}$ fb.

[11] AABOUD 18T search for $t\overline{t}H$ production with H decaying to $b\overline{b}$ in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

[12] SIRUNYAN 18BD search for $t\overline{t}H$, $H \to b\overline{b}$ in the all-jet final state with 35.9 fb^{-1} pp collision data at $E_{cm} = 13$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

[13] SIRUNYAN 18BQ search for $t\overline{t}H$ in final states with electrons, muons and hadronically decaying τ leptons ($H \to WW^*$, ZZ^*, $\tau\tau$) with 35.9 fb^{-1} of pp collision data at $E_{cm} = 13$ TeV. The quoted signal strength corresponds to a significance of 3.2 standard deviations and is given for $m_H = 125$ GeV.

[14] SIRUNYAN 18L use up to 5.1, 19.7 and 35.9 fb^{-1} of pp collisions at $E_{cm} = 7$, 8, and 13 TeV, respectively. The quoted signal strength corresponds to a significance of 5.2 standard deviations and is given for $m_H = 125.09$ GeV. H decay channels of WW^*, ZZ^*, $\gamma\gamma$, $\tau\tau$, and $b\overline{b}$ are used. See their Table 1 and Fig. 2 for results on individual channels.

[15] AAD 16AL search for $t\overline{t}H$ production with H decaying to $\gamma\gamma$ in 4.5 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and $b\overline{b}$, $\tau\tau$, $\gamma\gamma$, WW^*, and ZZ^* in 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125$ GeV. This paper combines the results of previous papers, and the new result of this paper only is: $\mu = 1.6 \pm 2.6$.

[16] AAD 16AN perform fits to the ATLAS and CMS data at $E_{cm} = 7$ and 8 TeV.

[17] AAD 16K use up to 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and up to 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The third uncertainty in the measurement is theory systematics. The quoted signal strength is given for $m_H = 125.36$ GeV.

[18] AAD 15 search for $t\overline{t}H$ production with H decaying to $\gamma\gamma$ in 4.5 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 20.3 fb^{-1} at $E_{cm} = 8$ TeV. The quoted result on the signal strength is equivalent to an upper limit of 6.7 at 95% CL and is given for $m_H = 125.4$ GeV.

[19] AAD 15BC search for $t\overline{t}H$ production with H decaying to $b\overline{b}$ in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. The corresponding upper limit is 3.4 at 95% CL. The quoted signal strength is given for $m_H = 125$ GeV.

[20] AAD 15T search for $t\overline{t}H$ production with H resulting in multilepton final states (mainly from WW^*, $\tau\tau$, ZZ^*) in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. The quoted result on the signal strength is given for $m_H = 125$ GeV and corresponds to an upper limit of 4.7 at 95% CL. The data sample is independent from AAD 15 and AAD 15BC.

[21] KHACHATRYAN 15AN search for $t\overline{t}H$ production with H decaying to $b\overline{b}$ in 19.5 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. The quoted result on the signal strength is equivalent to an upper limit of 4.2 at 95% CL and is given for $m_H = 125$ GeV.

[22] KHACHATRYAN 14H search for $t\overline{t}H$ production with H decaying to $b\overline{b}$, $\tau\tau$, $\gamma\gamma$, WW^*, and ZZ^*, in 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.7 fb^{-1} at $E_{cm} = 8$ TeV. The quoted signal strength is given for $m_H = 125.6$ GeV.

[23] AALTONEN 13L combine all CDF results with 9.45–10.0 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The quoted signal strength is given for $m_H = 125$ GeV.

[24] CHATRCHYAN 13X search for $t\overline{t}H$ production followed by $H \to b\overline{b}$, one top decaying to $\ell\nu$ and the other to either $\ell\nu$ or $q\overline{q}$ in 5.0 fb^{-1} and 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ and 8 TeV. A limit on cross section times branching ratio which corresponds to (4.0–8.6) times the expected Standard Model cross section is given for $m_H = 110$–140 GeV at 95% CL. The quoted limit is given for $m_H = 125$ GeV, where 5.2 is expected for no signal.

HH Production Cross Section in pp Collisions

The HH production cross section relative to the SM prediction.

[1] AAD 23AT combine results from 126–139 fb^{-1} of data at $E_{cm} = 13$ TeV for $pp \to HH \to b\overline{b}b\overline{b}$ (AAD 23BK), $b\overline{b}\tau\tau$ (AAD 23Z), and $b\overline{b}\gamma\gamma$ (AAD 22Y).

[2] AAD 23AD search for non-resonant HH production in association with a vector boson using $HH \to b\overline{b}b\overline{b}$ with data of 139 fb^{-1} at $E_{cm} = 13$ TeV. The vector boson decays leptonically ($W \to \ell\nu$, $Z \to \ell\ell, \nu\nu$, $\ell = e, \mu$).

[3] AAD 23BK search for non-resonant HH production using $HH \to b\overline{b}b\overline{b}$ with data of 126 fb^{-1} at $E_{cm} = 13$ TeV.

[4] AAD 23Z search for non-resonant HH production using $HH \to b\overline{b}\tau\tau$ with data of 139 fb^{-1} at $E_{cm} = 13$ TeV. The upper limit on the $pp \to HH$ production cross section at 95% CL is measured to be 140 fb, which corresponds to 4.7 times the SM prediction (see their Table 6).

[5] TUMASYAN 23AE search for HH production using $HH \to b\overline{b}b\overline{b}$, where both $b\overline{b}$ pairs are highly boosted, with data of 138 fb^{-1} at $E_{cm} = 13$ TeV.

[6] TUMASYAN 23D search for non-resonant HH production using $HH \to b\overline{b}\tau\tau$ with data of 138 fb^{-1} at $E_{cm} = 13$ TeV.

[7] The upper limit on the $pp \to HH$ production cross section (gluon fusion and VBF) at 95% CL is measured to be 102 fb, which corresponds to 3.3 times the SM prediction (see their Table 2).

[8] The upper limit on the VBF $pp \to HH$ production cross section at 95% CL is measured to be 212 fb, which corresponds to 124 times the SM prediction (see their Table 3).

[9] TUMASYAN 23I search for non-resonant HH production using $HH \to b\overline{b}ZZ^*$ ($ZZ^* \to 4\ell$, $\ell = e, \mu$) with data of 138 fb^{-1} at $E_{cm} = 13$ TeV.

[10] TUMASYAN 23O search for non-resonant HH production using $HH \to WW^*WW^*$, $WW^*\tau\tau$, and $\tau\tau\tau\tau$ (multilepton) with data of 138 fb^{-1} at $E_{cm} = 13$ TeV. See their Fig. 9 for different final states and these combination.

[11] AAD 22Y search for non-resonant HH production using $HH \to \gamma\gamma b\overline{b}$ with data of 139 fb^{-1} at $E_{cm} = 13$ TeV. The upper limit on the $pp \to HH$ production cross section at 95% CL is measured to be 130 fb, which corresponds to 4.2 times the SM prediction.

[12] CMS 22 report combined results (see their Extended Data Table 2) using 138 fb^{-1} of data at $E_{cm} = 13$ TeV. See their Fig. 5 (left) for different final states and these combination.

[13] TUMASYAN 22AN search for non-resonant HH production using $HH \to b\overline{b}b\overline{b}$ with data of 138 fb^{-1} at $E_{cm} = 13$ TeV. The upper limit on the $pp \to HH$ production cross section at 95% CL is measured to be 120 fb, which corresponds to 3.9 times the SM prediction.

[14] SIRUNYAN 21K search for non-resonant HH production using $HH \to \gamma\gamma b\overline{b}$ with data of 137 fb^{-1} at $E_{cm} = 13$ TeV. The upper limit on the $pp \to HH \to \gamma\gamma b\overline{b}$ production cross section at 95% CL is measured to be 0.67 fb, which corresponds to about 7.7 times the SM prediction.

[15] AAD 20C combine results of up to 36.1 fb^{-1} data at $E_{cm} = 13$ TeV for $pp \to HH \to b\overline{b}\gamma\gamma$, $b\overline{b}\tau\tau$, $b\overline{b}b\overline{b}$, $b\overline{b}WW^*$, $WW^*\gamma\gamma$, WW^*WW^* (AABOUD 18CW, AABOUD 18CQ, AABOUD 19A, AABOUD 19O, AABOUD 18BU, and AABOUD 19T).

[16] AAD 20E search non-resonant for HH production using $HH \to b\overline{b}\ell\nu\ell\nu$, where one of the Higgs bosons decays to $b\overline{b}$ and the other decays to either WW^*, ZZ^*, or $\tau\tau$, with data of 139 fb^{-1} at $E_{cm} = 13$ TeV. The upper limit on the $pp \to HH$ production cross section at 95% CL is measured to be 1.2 pb, which corresponds to about 40 times the SM prediction.

[17] AAD 20X search for $HH \to b\overline{b}b\overline{b}$ process via VBF with data of 126 fb^{-1} at $E_{cm} = 13$ TeV. The upper limit on the SM non-resonant HH production cross section is 1460 fb at 95% CL, which corresponds to 840 times the SM prediction.

[18] AABOUD 19A search for HH production using $HH \to b\bar{b}b\bar{b}$ with data of 36.1 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH \to b\bar{b}b\bar{b}$ production cross section at 95% is measured to be 147 fb, which corresponds to about 12.9 times the SM prediction.

[19] AABOUD 19O search for HH production using $HH \to b\bar{b}WW^*$ with data of 36.1 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH$ production cross section at 95% CL is calculated to be 10 pb from the observed upper limit on the $pp \to HH \to b\bar{b}WW^*$ production cross section of 2.5 pb assuming the SM branching fractions. The former corresponds to about 300 times the SM prediction.

[20] AABOUD 19T search for HH production using $HH \to WW^*WW^*$ with data of 36.1 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH$ production cross section at 95% is measured to be 5.3 pb, which corresponds to about 160 times the SM prediction.

[21] SIRUNYAN 19 search for HH production using $HH \to \gamma\gamma b\bar{b}$ with data of 35.9 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH \to \gamma\gamma b\bar{b}$ production cross section at 95% CL is measured to be 2.0 fb, which corresponds to about 24 times the SM prediction.

[22] SIRUNYAN 19AB search for HH production using $HH \to b\bar{b}b\bar{b}$, where 4 heavy flavor jets from two Higgs bosons are resolved, with data of 35.9 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH \to b\bar{b}b\bar{b}$ production cross section at 95% is measured to be 847 fb, which corresponds to about 75 times the SM prediction.

[23] SIRUNYAN 19BE combine results of 13 TeV 35.9 fb^{-1} data: SIRUNYAN 19, SIRUNYAN 18A, SIRUNYAN 19AB, SIRUNYAN 19H, and SIRUNYAN 18F.

[24] SIRUNYAN 19H search for HH production using $HH \to b\bar{b}b\bar{b}$, where one of $b\bar{b}$ pairs is highly boosted and the other one is resolved, with data of 35.9 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH \to b\bar{b}b\bar{b}$ production cross section at 95% is measured to be 1980 fb, which corresponds to about 179 times the SM prediction.

[25] AABOUD 18BU search for HH production using $\gamma\gamma WW^*$ with the final state of $\gamma\gamma\ell\nu jj$ using data of 36.1 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH$ production cross section at 95% CL is measured to be 7.7 pb, which corresponds to about 230 times the SM prediction. The upper limit on the $pp \to HH \to \gamma\gamma WW^*$ at 95% CL is measured to be 7.5 fb (see thier Table 6).

[26] AABOUD 18CQ search for HH production using $HH \to b\bar{b}\tau\tau$ with data of 36.1 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH \to b\bar{b}\tau\tau$ production cross section at 95% is measured to be 30.9 fb, which corresponds to about 12.7 times the SM prediction.

[27] AABOUD 18CW search for HH production using $HH \to \gamma\gamma b\bar{b}$ with data of 36.1 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH$ production cross section at 95% is measured to be 0.73 pb, which corresponds to about 22 times the SM prediction.

[28] SIRUNYAN 18A search for HH production using $HH \to b\bar{b}\tau\tau$ with data of 35.9 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $gg \to HH \to b\bar{b}\tau\tau$ production cross section is measured to be 75.4 fb, which corresponds to about 30 times the SM prediction.

[29] SIRUNYAN 18F search non-resonant for HH production using $HH \to b\bar{b}\ell\nu\ell\nu$, where $\ell\nu\ell\nu$ is either $WW \to \ell\nu\ell\nu$ or $ZZ \to \ell\ell\nu\nu$ (ℓ is e, μ or a leptonically decaying τ), with data of 35.9 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $HH \to b\bar{b}\ell\nu\ell\nu$ production cross section at 95% CL is measured to be 72 fb, which corresponds to about 79 times the SM prediction.

[30] SIRUNYAN 17CN search for HH production using $HH \to b\bar{b}\tau\tau$ with data of 18.3 fb^{-1} at E_{cm} = 8 TeV. Results are then combined with the published results of the $HH \to \gamma\gamma b\bar{b}$ and $HH \to b\bar{b}b\bar{b}$, which use data of up to 19.7 fb^{-1} at E_{cm} = 8 TeV. The upper limit on the $gg \to HH$ production cross section is measured to be 0.59 pb from $b\bar{b}\tau\tau$, which corresponds to about 59 times the SM prediction (gluon fusion). The combined upper limit is 0.43 pb, which is about 43 times the SM prediction. The quoted values are given for m_H = 125 GeV.

[31] AABOUD 16I search for HH production using $HH \to b\bar{b}b\bar{b}$ with data of 3.2 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH \to b\bar{b}b\bar{b}$ production cross section is measured to be 1.22 pb. This result corresponds to about 108 times the SM prediction (gluon fusion), which is $11.3^{+0.9}_{-1.0}$ fb (NNLO+NNLL) including top quark mass effects. The quoted values are given for m_H = 125 GeV .

[32] KHACHATRYAN 16BQ search for HH production using $HH \to \gamma\gamma b\bar{b}$ with data of 19.7 fb^{-1} at E_{cm} = 8 TeV. The upper limit on the $gg \to HH \to \gamma\gamma b\bar{b}$ production is measured to be 1.85 fb, which corresponds to about 74 times the SM prediction and is translated into 0.71 pb for $gg \to HH$ production cross section.

[33] AAD 15CE search for HH production using $HH \to b\bar{b}\tau\tau$ and $HH \to \gamma\gamma WW$ with data of 20.3 fb^{-1} at E_{cm} = 8 TeV. These results are then combined with the published results of the $HH \to \gamma\gamma b\bar{b}$ and $HH \to b\bar{b}b\bar{b}$, which use data of up to 20.3 fb^{-1} at E_{cm} = 8 TeV. The upper limits on the $gg \to HH$ production cross section are measured to be 1.6 pb, 11.4 pb, 2.2 pb and 0.62 pb from $b\bar{b}\tau\tau$, $\gamma\gamma WW$, $\gamma\gamma b\bar{b}$ and $b\bar{b}b\bar{b}$, respectively. The combined upper limit is 0.69 pb, which corresponds to about 70 times the SM prediction. The quoted results are given for m_H = 125.4 GeV. See their Table 4.

Higgs trilinear self coupling modifier κ_λ

Signal strength relative to the SM prediction, $\kappa_\lambda = \lambda_{HHH} / \lambda^{SM}_{HHH}$.

[1] AAD 23AD search for non-resonant HH production in association with a vector boson using $HH \to b\bar{b}b\bar{b}$ with data of 139 fb^{-1} at E_{cm} = 13 TeV. The vector boson decays leptonically ($W \to \ell\nu$, $Z \to \ell\ell$, $\nu\nu$, $\ell = e$, μ). The quoted κ_λ is measured assuming all other Higgs boson couplings are at their SM value.

[2] AAD 23AT combine results from 126–139 fb^{-1} of data at E_{cm} = 13 TeV for $pp \to HH \to b\bar{b}b\bar{b}$ (AAD 23BK), $b\bar{b}\tau\tau$ (AAD 23Z), and $b\bar{b}\gamma\gamma$ (AAD 22Y). The quoted values are obtained from the profile likelihood scan as a function of κ_λ as shown in their Fig. 5(a). All other coupling modifiers are assumed to have their SM values.

[3] AAD 23AT combine results from 126–139 fb^{-1} of data at E_{cm} = 13 TeV for $pp \to HH \to b\bar{b}b\bar{b}$ (AAD 23BK), $b\bar{b}\tau\tau$ (AAD 23Z), and $b\bar{b}\gamma\gamma$ (AAD 22Y) with single-Higgs boson analyses ($\gamma\gamma$, ZZ^*, WW^*, $\tau\tau$, $b\bar{b}$, see their Table 1). The quoted values are obtained from the profile likelihood scan as a function of κ_λ as shown in their Fig. 5(a), assuming that all other Higgs boson couplings are at their SM values. Results with other assumptions are shown in their Table 2.

[4] AAD 23BK search for non-resonant HH production using $HH \to b\bar{b}b\bar{b}$ with data of 126 fb^{-1} at E_{cm} = 13 TeV. The quoted values are obtained from the one-dimensional profile likelihood scan as a function of κ_λ. See their Fig. 12 (a). The $\mu_{ggF+VBF}$ measurement for different values of κ_λ constrains $-3.9 < \kappa_\lambda < 11.1$ at 95% CL as shown in their Fig. 10 (a). $\kappa_{2V} = \kappa_V = 1$ is assumed in both cases.

[5] HAYRAPETYAN 23 measure the cross sections for $pp \to H \to ZZ^* \to 4\ell$ ($\ell = e$, μ) using 138 fb^{-1} at E_{cm} = 13 TeV.

[6] TUMASYAN 23AE search for HH production using $HH \to b\bar{b}b\bar{b}$, where both $b\bar{b}$ pairs are highly boosted, with data of 138 fb^{-1} at E_{cm} = 13 TeV. The quoted κ_λ is measured assuming all other Higgs boson couplings are at their SM values.

[7] TUMASYAN 23D search for non-resonant HH production using $HH \to b\bar{b}\tau\tau$ with data of 138 fb^{-1} at E_{cm} = 13 TeV. The quoted values are obtained from the upper limit on the HH production cross section times the $b\bar{b}\tau\tau$ branching fraction for different values of κ_λ. See their Fig. 8 (left). All other coupling modifiers are assumed to be 1. In addition, two-dimensional exclusion regions as a function of the κ_λ and κ_t couplings, with $\kappa_{2V} = \kappa_V = 1$, are shown in their Fig. 9 (left). The one-dimensional likelihood scan as a function of κ_λ is given in their Fig 10 (left), from which a 95% confidence interval of $-1.77 < \kappa_\lambda < 8.73$ is extracted.

[8] TUMASYAN 23AI search for non-resonant HH production using $HH \to b\bar{b}ZZ^*$ ($ZZ^* \to 4\ell$, ℓ=e,μ) with data of 138 fb^{-1} at E_{cm} = 13 TeV. See their Fig. 4.

[9] TUMASYAN 23O search for non-resonant HH production using $HH \to WW^*WW^*$, $WW^*\tau\tau$, and $\tau\tau\tau\tau$ (multilepton) with data of 138 fb^{-1} at E_{cm} = 13 TeV. See their Fig. 10 for different final states and these combination. Limits are set on a variety of new-physics models using an effective field theory approach. See their Figs. 11, 12, and 13.

[10] AAD 22Y search for non-resonant HH production using $HH \to \gamma\gamma b\bar{b}$ with data of 139 fb^{-1} at E_{cm} = 13 TeV. The quoted κ_λ is obtained from their Fig. 12 where the theory uncertainties are not included while a negative log-likelihood scan vs. $\kappa_\lambda$is shown in their Fig. 13 with the theory uncertainties, which provides $\kappa_\lambda = 2.8^{+2.0}_{-2.2}$ for the 1σ confidence interval.

[11] CMS 22 report combined results (see their Extended Data Table 2) using 138 fb^{-1} of data at E_{cm} = 13 TeV. See their Fig. 6 (left).

[12] TUMASYAN 22AN search for non-resonant HH production using $HH \to b\bar{b}b\bar{b}$ with data of 138 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH$ production cross section at 95% CL is shown as a function of κ_λ in their Fig. 2 (top).

[13] SIRUNYAN 21K search for non-resonant HH production using $HH \to \gamma\gamma b\bar{b}$ with data of 137 fb^{-1} at E_{cm} = 13 TeV.

[14] AAD 20C combine results of up to 36.1 fb^{-1} data at E_{cm} = 13 TeV for $pp \to HH \to b\bar{b}\gamma\gamma$, $b\bar{b}\tau\tau$, $b\bar{b}b\bar{b}$, $b\bar{b}WW^*$, $WW^*\gamma\gamma$, WW^*WW^* (AABOUD 18CW, AABOUD 18CQ, AABOUD 19A, AABOUD 19O, AABOUD 18BU, and AABOUD 19T).

[15] SIRUNYAN 19 search for HH production using $HH \to \gamma\gamma b\bar{b}$ with data of 35.9 fb^{-1} at E_{cm} = 13 TeV. The quoted κ_λ is measured assuming all other Higgs boson couplings are at their SM value.

[16] SIRUNYAN 19BE combine results of 13 TeV 35.9 fb^{-1} data: SIRUNYAN 19, SIRUNYAN 18A, SIRUNYAN 19AB, SIRUNYAN 19H, and SIRUNYAN 18F.

[17] AABOUD 18CW search for HH production using $HH \to \gamma\gamma b\bar{b}$ with data of 36.1 fb^{-1} at E_{cm} = 13 TeV. The quoted κ_λ is measured assuming all other Higgs boson couplings are at their SM value.

[18] SIRUNYAN 18A search for HH production using $HH \to b\bar{b}\tau\tau$ with data of 35.9 fb^{-1} at E_{cm} = 13 TeV. The upper limit on production cross section times branching fraction at 95% CL is shown as a function of κ_λ/κ_t in their Fig. 6 (top) where $\kappa_t = y_t / y_t^{SM}$ (top Yukawa coupling y_t).

[19] KHACHATRYAN 16BQ search for HH production using $HH \to \gamma\gamma b\bar{b}$ with data of 19.7 fb^{-1} at E_{cm} = 8 TeV.

Higgs-gauge boson quartic coupling modifier κ_{2V}

Signal strength relative to the SM prediction, $\kappa_{2V} = \lambda_{VVHH} / \lambda^{SM}_{VVHH}$, $V = W, Z$.

[1] AAD 23AD search for non-resonant HH production in association with a vector boson using $HH \to b\bar{b}b\bar{b}$ with data of 139 fb^{-1} at E_{cm} = 13 TeV. The vector boson decays leptonically ($W \to \ell\nu$, $Z \to \ell\ell, \nu\nu$, $\ell = e,\ \mu$). The constraints on κ_{2W} and κ_{2Z} are separately measured to be -12.3 < κ_{2W} < 13.5 and -9.9 < κ_{2Z} < 11.3 (95% CL). The quoted κ_{2V} ($V = W,\ Z$) is measured assuming all other Higgs boson couplings are at their SM value.

[2] AAD 23AT combine results from 126–139 fb^{-1} of data at E_{cm} = 13 TeV for $pp \to HH \to b\bar{b}b\bar{b}$ (AAD 23BK), $b\bar{b}\tau\tau$ (AAD 23Z), and $b\bar{b}\gamma\gamma$ (AAD 22Y). The quoted values are obtained from the 95% CL VBF HH cross-section upper limit as a function of κ_{2V} as shown in their Fig. 4(b). All other coupling modifiers are assumed to have their SM values.

[3] AAD 23BK search for non-resonant HH production using $HH \to b\bar{b}b\bar{b}$ with data of 126 fb^{-1} at E_{cm} = 13 TeV. The quoted values are obtained from the one-dimensional profile likelihood scan as a function of κ_{2V}. See their Fig. 12 (b). The μ_{VBF} measurement for different values of κ_{2V} constrains -0.03 < κ_{2V} < 2.11 at 95% CL as shown in their Fig. 10 (b). $\kappa_\lambda = \kappa_V = 1$ is assumed in both cases.

[4] TUMASYAN 23AE search for HH production using $HH \to b\bar{b}b\bar{b}$, where both $b\bar{b}$ pairs are highly boosted, with data of 138 fb^{-1} at E_{cm} = 13 TeV. The $\kappa_{2V} = 0$ is excluded at 6.3 σ assuming all other Higgs boson couplings are at their SM values.

[5] TUMASYAN 23D search for non-resonant HH production using $HH \to b\bar{b}\tau\tau$ with data of 138 fb^{-1} at E_{cm} = 13 TeV. The quoted values are obtained from the upper limits on the HH production cross section times the $b\bar{b}\tau\tau$ branching fraction for different values of κ_{2V}. See their Fig. 8 (right). All other coupling modifiers are assumed to be 1. In addition, two-dimensional exclusion regions as a function of the κ_{2V} and κ_V couplings, with $\kappa_\lambda = \kappa_t = 1$, are shown in their Fig. 9 (right). The one-dimensional likelihood scan as a function of κ_{2V} is given in their Fig. 10 (right), from which a 95% confidence interval of -0.34 < κ_{2V} < 2.49 is extracted.

[6] CMS 22 report combined results (see their Extended Data Table 2) using 138 fb^{-1} of data at E_{cm} = 13 TeV. See their Fig. 6 (right).

[7] TUMASYAN 22AN search for non-resonant HH production using $HH \to b\bar{b}b\bar{b}$ with data of 138 fb^{-1} at E_{cm} = 13 TeV. The upper limit on the $pp \to HH$ production cross section at 95% CL is shown as a function of κ_{2V} in their Fig. 2 (bottom).

[8] SIRUNYAN 21K search for non-resonant HH production using $HH \to \gamma\gamma b\bar{b}$ with data of 137 fb^{-1} at E_{cm} = 13 TeV.

[9] AAD 20X search for $HH \to b\bar{b}b\bar{b}$ process via VBF with data of 126 fb^{-1} at E_{cm} = 13 TeV.

t H production

VALUE	*DOCUMENT ID*		*TECN*	*COMMENT*
5.7±2.7±3.0	[1] SIRUNYAN	21R	CMS	pp, 13 TeV
• • • We do not use the following data for averages, fits, limits, etc. • • •				
	[2] AAD	20Z	ATLS	pp, 13 TeV
	[3] SIRUNYAN	19BK	CMS	pp, 13 TeV
	[4] KHACHATRY...16AU		CMS	pp, 8 TeV

[1] SIRUNYAN 21R search for tH in final states with electrons, muons and hadronically decaying τ leptons ($H \to WW^*,\ ZZ^*,\ \tau\tau$) with 137 fb^{-1} of pp collision data at E_{cm} = 13 TeV. The quoted signal strength corresponds to a significance of 1.4 standard deviations and is given for m_H = 125 GeV.

[2] AAD 20Z search for the tH associated production using $H \to \gamma\gamma$ in 139 fb^{-1} of data at E_{cm} = 13 TeV. An upper limit on its rate is set to be 12 times the Standard Model at 95% CL (m_H = 125.09 GeV).

[3] SIRUNYAN 19BK search for the tH associated production using multilepton signatures ($H \to WW^*$, $H \to \tau\tau$, $H \to ZZ^*$) and signatures with a single lepton and a $b\bar{b}$ pair ($H \to b\bar{b}$) using 35.9 fb^{-1} at E_{cm} = 13 TeV. Results are combined with $H \to \gamma\gamma$ (SIRUNYAN 18DS). The observed 95% CL upper limit on the tH production cross section times $H \to WW^* + \tau\tau + ZZ^* + b\bar{b} + \gamma\gamma$ branching fraction is 1.94 pb (assuming SM $t\bar{t}H$ production cross section). See their Table X and Fig. 14. The values outside the ranges of [−0.9, −0.5] and [1.0, 2.1] times the standard model top quark Yukawa coupling are excluded at 95% CL.

[4] KHACHATRYAN 16AU search for the tH associated production in 19.7 fb^{-1} at E_{cm} = 8 TeV. The 95% CL upper limits on the tH associated production cross section is measured to be 600–1000 fb depending on the assumed $\gamma\gamma$ branching ratios of the Higgs boson. The $\gamma\gamma$ branching ratio is varied to be by a factor of 0.5–3.0 of the Standard Model Higgs boson (m_H = 125 GeV). The results of the signal strengths for a negative Higgs-boson trilinear coupling are given. The results are given for m_H = 125 GeV.

H Production Cross Section in *pp* Collisions at $\sqrt{s}$ = 13 TeV

Assumes m_H = 125 GeV

[1] AAD 23C combine AAD 22N and AAD 20BA, where both use 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. The Higgs production cross sections at E_{cm} = 7 and 8 TeV are obtained to be 34^{+11}_{-10} pb and $33.3^{+5.8}_{-5.4}$ pb, respectively. The quoted value is given for m_H = 125.09 GeV. The differential cross sections are given in their Figs. 3 and 4.

[2] SIRUNYAN 19BA use 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV.

[3] AAD 22N use 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. The quoted value is given for m_H = 125.09 GeV.

[4] AAD 20BA use 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV with $H \to ZZ^* \to 4\ell$ where $\ell = e,\ \mu$. The quoted value is given for m_H = 125 GeV and assumes the Standard Model branching ratio.

[5] AABOUD 18CG use 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV.

[6] AABOUD 17CO use 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV with $H \to ZZ^* \to 4\ell$ where $\ell = e,\ \mu$ for m_H = 125 GeV. Differential cross sections for the Higgs boson transverse momentum, Higgs boson rapidity, and other related quantities are measured as shown in their Figs. 8 and 9.

MASS LIMITS FOR NEUTRAL HIGGS BOSONS IN SUPERSYMMETRIC MODELS

The minimal supersymmetric model has two complex doublets of Higgs bosons. The resulting physical states are two scalars [H_1^0 and H_2^0, where we define $m_{H_1^0} < m_{H_2^0}$], a pseudoscalar (A^0), and a charged Higgs pair ($H^\pm$). H_1^0 and H_2^0 are also called h and H in the literature. There are two free parameters in the Higgs sector which can be chosen to be m_{A^0} and $\tan\beta = v_2/v_1$, the ratio of vacuum expectation values of the two Higgs doublets. Tree-level Higgs masses are constrained by the model to be $m_{H_1^0} \leq m_Z$, $m_{H_2^0} \geq m_Z$, $m_{A^0} \geq m_{H_1^0}$, and $m_{H^\pm} \geq m_W$. However, as described in the review on "Status of Higgs Boson Physics" in this Volume these relations are violated by radiative corrections.

The observed signal at about 125 GeV, see section "*H*", can be interpreted as one of the neutral Higgs bosons of supersymmetric models. Unless otherwise noted, we identify the lighter scalar H_1^0 with the Higgs discovered at 125 GeV at the LHC (AAD 12AI, CHATRCHYAN 12N).

Unless otherwise noted, the experiments in e^+e^- collisions search for the processes $e^+e^- \to H_1^0 Z^0$ in the channels used for the Standard Model Higgs searches and $e^+e^- \to H_1^0 A^0$ in the final states $b\overline{b}b\overline{b}$ and $b\overline{b}\tau^+\tau^-$. Unless otherwise stated, the following results assume no invisible H_1^0 or A^0 decays. Unless otherwise noted, the results are given in the m_h^{max} scenario, CARENA 13.

In $p\overline{p}$ and pp collisions the experiments search for a variety of processes, as explicitly specified for each entry. Limits on the A^0 mass arise from these direct searches, as well as from the relations valid in the minimal supersymmetric model between m_{A^0} and $m_{H_1^0}$. As discussed in the review on "Status of Higgs Boson Physics" in this Volume, these relations

Gauge & Higgs Boson Particle Listings

Neutral Higgs Bosons, Searches for

depend, via potentially large radiative corrections, on the mass of the t quark and on the supersymmetric parameters, in particular those of the stop sector. These indirect limits are weaker for larger t and $\tilde{t}$ masses. To include the radiative corrections to the Higgs masses, unless otherwise stated, the listed papers use theoretical predictions incorporating two-loop corrections and beyond (SLAVICH 21), and the results are given for the M_h^{125} benchmark scenario, see BAGNASCHI 19.

Mass Limits for heavy neutral Higgs bosons (H_2^0, A^0) in the MSSM

The limits rely on $pp \to H_2^0/A^0 \to \tau^+\tau^-$ and assume that H_2^0 and A^0 are (sufficiently) mass degenerate. The limits depend on $\tan\beta$.

[1] TUMASYAN 23S search for production of $H_2^0/A^0 \to \tau^+\tau^-$ by gluon fusion and b-associated prodution using 138 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 13 for excluded regions in the m_{A^0}–$\tan\beta$ plane in M_h^{125} and M_{hEFT}^{125} MSSM scenarios. In both scenarios $m_{A^0} < 350$ GeV is excluded at 95% CL.

[2] AAD 20AA search for $H_2^0/A^0 \to \tau^+\tau^-$ produced by gluon fusion or b-associated production using 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 2(c) for excluded region in the M_h^{125} scenario of MSSM. Values of $\tan\beta > 8$ (21) are excluded for $m_{A^0} = 1.0$ (1.5) TeV at 95%CL.

[3] AAD 20 combine measurements on H^0 production and decay using data taken in years 2015–2017 (up to 79.8 fb^{-1}) of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 19 for excluded region in the hMSSM parameter space.

[4] AAD 20C combine searches for a scalar resonance decaying to $H^0 H^0$ in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV from AABOUD 19A, AABOUD 19O, AABOUD 18CQ, AABOUD 19T, AABOUD 18CW, and AABOUD 18BU. See their Fig. 7(b) for the excluded region in the hMSSM parameter space.

[5] AAD 20L search for b-associated production of H_2^0 decaying to $b\overline{b}$ in 27.8 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 9 for excluded regions in hMSSM, m_h^{mod+} and m_h^{mod-} scenarios of MSSM.

[6] SIRUNYAN 20AC search for gluon-fusion and b-associated production of A^0 decaying to $Z H^0$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 6 for excluded regions in the M_{hEFT}^{125} and hMSSM scenarios of the MSSM.

[7] SIRUNYAN 20AF search for $H_2^0/A^0 \to t\overline{t}$ with one or two charged leptons in the final state using kinematic variables in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 8 for excluded region in the hMSSM scenario of MSSM. Values of $\tan\beta$ below 1.0–1.5 are excluded for $m_{A^0} = 0.4$–0.75 TeV at 95%CL.

[8] SIRUNYAN 20Y search for gluon-fusion and vector-boson-fusion production of H_2^0 decaying to $W^+ W^-$ in the final states $\ell\nu\ell\nu$ and $\ell\nu qq$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Figs. 8 and 9 for excluded regions in various MSSM scenarios.

[9] SIRUNYAN 19CR search for production of H_2^0/A^0 in gluon fusion and in association with a $b\overline{b}$ pair, decaying to $\mu^+\mu^-$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5 for the excluded region in the MSSM parameter space in the m_h^{mod+} and hMSSM scenarios.

[10] AABOUD 18G search for production of $H_2^0/A^0 \to \tau^+\tau^-$ by gluon fusion and b-associated prodution in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 10 for excluded regions in the m_{A^0}– $\tan\beta$ plane in several MSSM scenarios.

[11] SIRUNYAN 18A search for production of a scalar resonance decaying to $H^0 H^0 \to b\overline{b}\tau^+\tau^-$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5 (lower) for excluded regions in the $m_{A^0} - \tan\beta$ plane in the hMSSM scenario.

[12] SIRUNYAN 18BP search for production of $H_2^0/A^0 \to b\overline{b}$ by b-associated prodution in 35.7 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 6 for the limits on cross section times branching ratio for $m_{H_2^0}$, $m_{A^0} = 0.3$–1.3 TeV, and Fig. 7 for excluded regions in the m_{A^0}– $\tan(\beta)$ plane in several MSSM scenarios.

[13] SIRUNYAN 18CX search for production of $H_{1,2}^0/A^0 \to \tau^+\tau^-$ by gluon fusion and b-associated prodution in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 9 for excluded regions in the m_{A^0}– $\tan(\beta)$ plane in several MSSM scenarios.

[14] AABOUD 16AA search for production of a Higgs boson in gluon fusion and in association with a $b\overline{b}$ pair followed by the decay $A^0 \to \tau^+\tau^-$ in 3.2 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5(a, b) for limits on cross section times branching ratio for $m_{A^0} = 200$–1200 GeV, and Fig. 5(c, d) for the excluded region in the MSSM parameter space in the m_h^{mod+} and hMSSM scenarios.

[15] KHACHATRYAN 16A search for production of a Higgs boson in gluon fusion and in association with a $b\overline{b}$ pair followed by the decay $H_{1,2}^0/A^0 \to \mu^+\mu^-$ in 5.1 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV and 19.3 fb^{-1} at $E_{cm} = 8$ TeV. See their Fig. 7 for the excluded region in the MSSM parameter space in the m_h^{mod+} benchmark scenario and Fig. 9 for limits on cross section times branching ratio.

[16] KHACHATRYAN 16P search for gluon fusion production of an H_2^0 decaying to $H^0 H^0 \to b\overline{b}\tau^+\tau^-$ and an A^0 decaying to $Z H^0 \to \ell^+\ell^-\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 12 for excluded region in the $\tan\beta - \cos(\beta - \alpha)$ plane for $m_{H_2^0} = m_{A^0} = 300$ GeV.

[17] KHACHATRYAN 15AY search for production of a Higgs boson in association with a b quark in the decay $H_{1,2}^0/A^0 \to b\overline{b}$ in 19.7 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV and combine with CHATRCHYAN 13AG 7 TeV data. See their Fig. 6 for the limits on cross section times branching ratio for $m_{A^0} = 100$–900 GeV and Figs. 7–9 for the excluded region in the MSSM parameter space in various benchmark scenarios.

[18] AAD 14AW search for production of a Higgs boson followed by the decay $H_{1,2}^0/A^0 \to \tau^+\tau^-$ in 19.5–20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 11 for the limits on cross section times branching ratio and their Figs. 9 and 10 for the excluded region in the MSSM parameter space. For $m_{A^0} = 140$ GeV, the region $\tan\beta > 5.4$ is excluded at 95% CL in the m_h^{max} scenario.

[19] KHACHATRYAN 14M search for production of a Higgs boson in gluon fusion and in association with a b quark followed by the decay $H^0_{1,2}/A^0 \to \tau^+\tau^-$ in 4.9 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.7 fb^{-1} at E_{cm} = 8 TeV. See their Figs. 7 and 8 for one- and two-dimensional limits on cross section times branching ratio and their Figs. 5 and 6 for the excluded region in the MSSM parameter space. For m_{A^0} = 140 GeV, the region tan$\beta > 3.8$ is excluded at 95% CL in the m_h^{max} scenario.

[20] AAD 13O search for production of a Higgs boson in the decay $H^0_{1,2}/A^0 \to \tau^+\tau^-$ and $\mu^+\mu^-$ with 4.7–4.8 fb^{-1} of pp collisions at E_{cm} = 7 TeV. See their Fig. 6 for the excluded region in the MSSM parameter space and their Fig. 7 for the limits on cross section times branching ratio. For m_{A^0} = 110–170 GeV, tan$\beta \gtrsim 10$ is excluded, and for tanβ = 50, m_{A^0} below 470 GeV is excluded at 95% CL in the m_h^{max} scenario.

[21] AAIJ 13T search for production of a Higgs boson in the forward region in the decay $H^0_{1,2}/A^0 \to \tau^+\tau^-$ in 1.0 fb^{-1} of pp collisions at E_{cm} = 7 TeV. See their Fig. 2 for the limits on cross section times branching ratio and the excluded region in the MSSM parameter space.

[22] CHATRCHYAN 13AG search for production of a Higgs boson in association with a b quark in the decay $H^0_{1,2}/A^0 \to b\overline{b}$ in 2.7–4.8 fb^{-1} of pp collisions at E_{cm} = 7 TeV. See their Fig. 6 for the excluded region in the MSSM parameter space and Fig. 5 for the limits on cross section times branching ratio. For m_{A^0} = 90–350 GeV, upper bounds on tanβ of 18–42 at 95% CL are obtained in the m_h^{max} scenario with $\mu = +200$ GeV.

[23] AALTONEN 12AQ combine AALTONEN 12X and ABAZOV 11K. See their Table I and Fig. 1 for the limit on cross section times branching ratio and Fig. 2 for the excluded region in the MSSM parameter space.

[24] AALTONEN 12X search for associated production of a Higgs boson and a b quark in the decay $H^0_{1,2}/A^0 \to b\overline{b}$, with 2.6 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. See their Table III and Fig. 15 for the limit on cross section times branching ratio and Figs. 17, 18 for the excluded region in the MSSM parameter space.

[25] ABAZOV 12G search for production of a Higgs boson in the decay $H^0_{1,2}/A^0 \to \tau^+\tau^-$ with 7.3 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV and combine with ABAZOV 11W and ABAZOV 11K. See their Figs. 4, 5, and 6 for the excluded region in the MSSM parameter space. For m_{A^0} = 90–180 GeV, tan$\beta \gtrsim 30$ is excluded at 95% CL. in the m_h^{max} scenario.

[26] CHATRCHYAN 12K search for production of a Higgs boson in the decay $H^0_{1,2}/A^0 \to \tau^+\tau^-$ with 4.6 fb^{-1} of pp collisions at E_{cm} = 7 TeV. See their Fig. 3 and Table 4 for the excluded region in the MSSM parameter space. For m_{A^0} = 160 GeV, the region tan$\beta > 7.1$ is excluded at 95% CL in the m_h^{max} scenario. Superseded by KHACHATRYAN 14M.

[27] ABAZOV 11K search for associated production of a Higgs boson and a b quark, followed by the decay $H^0_{1,2}/A^0 \to b\overline{b}$, in 5.2 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. See their Fig. 5/Table 2 for the limit on cross section times branching ratio and Fig. 6 for the excluded region in the MSSM parameter space for $\mu = -200$ GeV.

[28] ABAZOV 11W search for associated production of a Higgs boson and a b quark, followed by the decay $H^0_{1,2}/A^0 \to \tau\tau$, in 7.3 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. See their Fig. 2 for the limit on cross section times branching ratio and for the excluded region in the MSSM parameter space.

[29] AALTONEN 09AR search for Higgs bosons decaying to $\tau^+\tau^-$ in two doublet models in 1.8 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. See their Fig. 2 for the limit on $\sigma \cdot$ B($H^0_{1,2}/A^0 \to \tau^+\tau^-$) for different Higgs masses, and see their Fig. 3 for the excluded region in the MSSM parameter space.

[30] ABDALLAH 08B give limits in eight CP-conserving benchmark scenarios and some CP-violating scenarios. See paper for excluded regions for each scenario. Supersedes ABDALLAH 04.

[31] SCHAEL 06B make a combined analysis of the LEP data. The quoted limit is for the m_h^{max} scenario with m_t = 174.3 GeV. In the CP-violating CPX scenario no lower bound on $m_{H^0_1}$ can be set at 95% CL. See paper for excluded regions in various scenarios. See Figs. 2–6 and Tabs. 14–21 for limits on $\sigma(ZH^0)\cdot$ B($H^0 \to b\overline{b}, \tau^+\tau^-$) and $\sigma(H^0_1 H^0_2)\cdot$ B(H^0_1,$H^0_2 \to b\overline{b},\tau^+\tau^-$).

[32] ACOSTA 05Q search for $H^0_{1,2}/A^0$ production in $p\overline{p}$ collisions at E_{cm} = 1.8 TeV with $H^0_{1,2}/A^0 \to \tau^+\tau^-$. At m_{A^0} = 100 GeV, the obtained cross section upper limit is above theoretical expectation.

[33] Search for $e^+e^- \to H^0_1 A^0$ in the final states $b\overline{b}b\overline{b}$ and $b\overline{b}\tau^+\tau^-$, and $e^+e^- \to H^0_1 Z$. Universal scalar mass of 1 TeV, SU(2) gaugino mass of 200 GeV, and $\mu = -200$ GeV are assumed, and two-loop radiative corrections incorporated. The limits hold for m_t=175 GeV, and for the m_h^{max} scenario.

[34] ABBIENDI 04M exclude 0.7 < tanβ < 1.9, assuming m_t = 174.3 GeV. Limits for other MSSM benchmark scenarios, as well as for CP violating cases, are also given.

[35] ABBIENDI 03G search for $e^+e^- \to H^0_1 Z$ followed by $H^0_1 \to A^0A^0$, $A^0 \to c\overline{c}$, gg, or $\tau^+\tau^-$. In the no-mixing scenario, the region $m_{H^0_1}$ = 45-85 GeV and m_{A^0} = 2-9.5 GeV is excluded at 95% CL.

[36] ACHARD 02H also search for the final state $H^0_1 Z \to 2A^0 q\overline{q}$, $A^0 \to q\overline{q}$. In addition, the MSSM parameter set in the "large-μ" and "no-mixing" scenarios are examined.

[37] AKEROYD 02 examine the possibility of a light A^0 with tanβ <1. Electroweak measurements are found to be inconsistent with such a scenario.

[38] HEISTER 02 excludes the range 0.7 <tanβ < 2.3. A wider range is excluded with different stop mixing assumptions. Updates BARATE 01C.

[3] Search for $e^+e^- \to H^0_1 A^0$ in the final states $b\overline{b}b\overline{b}$ and $b\overline{b}\tau^+\tau^-$, and $e^+e^- \to H^0_1 Z$. Universal scalar mass of 1 TeV, SU(2) gaugino mass of 200 GeV, and $\mu = -200$ GeV are assumed, and two-loop radiative corrections incorporated. The limits hold for m_t=175 GeV, and for the m_h^{max} scenario.

[4] ABBIENDI 04M exclude 0.7 < tanβ < 1.9, assuming m_t = 174.3 GeV. Limits for other MSSM benchmark scenarios, as well as for CP violating cases, are also given.

[5] ACHARD 02H also search for the final state $H^0_1 Z \to 2A^0 q\overline{q}$, $A^0 \to q\overline{q}$. In addition, the MSSM parameter set in the "large-μ" and "no-mixing" scenarios are examined.

[6] HEISTER 02 excludes the range 0.7 <tanβ < 2.3. A wider range is excluded with different stop mixing assumptions. Updates BARATE 01C.

[7] AALTONEN 12AQ combine AALTONEN 12X and ABAZOV 11K. See their Table I and Fig. 1 for the limit on cross section times branching ratio and Fig. 2 for the excluded region in the MSSM parameter space.

MASS LIMITS FOR NEUTRAL HIGGS BOSONS IN EXTENDED HIGGS MODELS

This Section covers models which do not fit into either the Standard Model or its simplest minimal Supersymmetric extension (MSSM), leading to anomalous production rates, or nonstandard final states and branching ratios. In particular, this Section covers limits which may apply to generic two-Higgs-doublet models (2HDM), or to special regions of the MSSM parameter space where decays to invisible particles or to photon pairs are dominant (see the review on "Status of Higgs Boson Physics"). Concerning the mass limits for H^0 and A^0 listed below, see the footnotes or the comment lines for details on the nature of the models to which the limits apply.

The observed signal at about 125 GeV, see section "H", can be interpreted as one of the neutral Higgs bosons of an extended Higgs sector.

Mass Limits in General two-Higgs-doublet Models

[1] AAD 23AD search for associated production of WZH^0_2 and gluon fusion production of A^0 decaying to ZH^0_2, with the decay chain $H^0_2 \to HH \to b\overline{b}b\overline{b}$, using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 12 and 13 for excluded regions in Type-I and lepton-specific 2HDMs.

[2] AAD 23BG search for production of H^0_2/A^0 in association with a $t\overline{t}$ pair, decaying to $t\overline{t}$, using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 8 for excluded regions in the parameter space of the type II 2HDM.

[3] AAD 23O search for production of an A^0 in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to ZH in the final states $\nu\overline{\nu}b\overline{b}$ and $\ell^+\ell^-b\overline{b}$ using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 12 and 13 for excluded regions in the parameter space in various 2HDMs.

[4] AAD 21AF search for production of a heavy H^0_2 state decaying to ZZ in the final states $\ell^+\ell^-\ell'^+\ell'^-$ and $\ell^+\ell^-\nu\overline{\nu}$ in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 6 and 7 for excluded parameter regions of the 2HDM Type I and II.

[5] AAD 21AI search for production of an A^0 in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to $ZH^0_2 \to \ell^+\ell^-b\overline{b}$ or $\ell^+\ell^-W^+W^-$ in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 10 and 14 for excluded regions in the parameter space of various 2HDMs.

[6] AAD 20 combine measurements on H^0 production and decay using data taken in years 2015–2017 (up to 79.8 fb^{-1}) of pp collisions at E_{cm} = 13 TeV. See their Fig. 18 for excluded regions in various 2HDMs.

[7] AAD 20L search for b-associated production of H^0_2 decaying to $b\overline{b}$ in 27.8 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 10 and 11 for excluded regions in the flipped two Higgs doublet model.

[8] SIRUNYAN 20AA search for $H^0_2 \to ZA^0$, $A^0 \to b\overline{b}$ or $A^0 \to ZH^0_2$, $H^0_2 \to b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 8 and 9 for excluded regions in the parameter space of Type-II two Higgs doublet model.

[9] SIRUNYAN 20Y search for gluon-fusion and vector-boson-fusion production of H^0_2 decaying to W^+W^- in the final states $\ell\nu\ell\nu$ and $\ell\nu qq$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 7 for excluded regions in Type I and II two Higgs doublet models.

[10] SIRUNYAN 19AE search for a pseudoscalar resonance produced in association with a $b\overline{b}$ pair, decaying to $\tau^+\tau^-$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 4 for cross section limits for m_{A^0} = 25–70 GeV and comparison with some representative 2HDMs.

[11] SIRUNYAN 19AV search for a scalar resonance produced by gluon fusion or b associated production, decaying to $ZH^0 \to \ell^+\ell^-b\overline{b}$ (ℓ = e, μ) or $\nu\overline{\nu}b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 6 and 7 for excluded regions in the parameter space of various 2HDMs.

[12] AABOUD 18AH search for production of an A^0 in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to $ZH^0_2 \to \ell^+\ell^-b\overline{b}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6 for excluded regions in the parameter space of various 2HDMs.

[13] AABOUD 18AI search for production of an A^0 in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to ZH^0 in the final states $\nu\overline{\nu}b\overline{b}$ and $\ell^+\ell^-b\overline{b}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 7 and 8 for excluded regions in the parameter space in various 2HDMs.

[14] AABOUD 18BF search for production of a heavy H^0_2 state decaying to ZZ in the final states $\ell^+\ell^-\ell^+\ell^-$ and $\ell^+\ell^-\nu\overline{\nu}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 8 and 9 for excluded parameter regions in 2HDM Type I and II.

[15] AABOUD 18CE search for the process $pp \to H^0_2/A^0\,t\overline{t}$ followed by the decay $H^0_2/A^0 \to t\overline{t}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 12 for limits on cross section times branching ratio, and for lower limits on $\tan\beta$ for $m_{H^0_2}$, m_{A^0} = 0.4–1.0 TeV in the 2HDM type II.

[16] HALLER 18 perform global fits in the framework of two-Higgs-doublet models (type I, II, lepton specific, flipped). See their Fig. 8 for allowed parameter regions from fits to LHC H^0 measurements, Fig. 9 bottom and charm decays, Fig. 10 muon anomalous magnetic moment, Fig. 11 electroweak precision data, and Fig. 12 by combination of all data.

[17] SIRUNYAN 18BP search for production of $H^0_2/A^0 \to b\overline{b}$ by b-associated prodution in 35.7 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6 for the limits on cross section times branching ratio for $m_{H^0_2}$, m_{A^0} = 0.3–1.3 TeV, and Figs. 8 and 9 for excluded regions in the parameter space of type-II and flipped 2HDMs.

[18] SIRUNYAN 18ED search for production of an A^0 in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to ZH^0 in the final states $\nu\overline{\nu}b\overline{b}$ or $\ell^+\ell^-b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 9 for excluded regions in the parameter space in Type I and II 2HDMs.

[19] AABOUD 17AN search for production of a heavy H^0_2 and/or A^0 decaying to $t\overline{t}$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 3 and Table III for excluded parameter regions in Type II Two-Higgs-Doublet-Models.

[20] SIRUNYAN 17AX search for $A^0\,b\overline{b}$ production followed by the decay $A^0 \to \mu^+\mu^-$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. Limits are set in the range m_{A^0} = 25–60 GeV. See their Fig. 5 for upper limits on $\sigma(A^0\,b\overline{b})\cdot$B($A^0 \to \mu^+\mu^-$).

[21] AAD 16AX search for production of a heavy H^0 state decaying to ZZ in the final states $\ell^+\ell^-\ell^+\ell^-$, $\ell^+\ell^-\nu\overline{\nu}$, $\ell^+\ell^-q\overline{q}$, and $\nu\overline{\nu}q\overline{q}$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Figs. 13 and 14 for excluded parameter regions in Type I and II models.

[22] KHACHATRYAN 16P search for gluon fusion production of an H^0_2 decaying to $H^0H^0 \to b\overline{b}\tau^+\tau^-$ and an A^0 decaying to $ZH^0 \to \ell^+\ell^-\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 11 for limits on $\tan\beta$ for m_{A^0} = 230–350 GeV.

[23] KHACHATRYAN 16W search for $A^0\,b\overline{b}$ production followed by the decay $A^0 \to \tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 3 for upper limits on $\sigma(A^0\,b\overline{b})\cdot$B($A^0 \to \tau^+\tau^-$).

[24] KHACHATRYAN 16Z search for $H^0_2 \to ZA^0$ followed by $A^0 \to b\overline{b}$ or $\tau^+\tau^-$, and $A^0 \to ZH^0_2$ followed by $H^0_2 \to b\overline{b}$ or $\tau^+\tau^-$, in 19.8 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 4 for cross section limits and Fig. 5 for excluded region in the parameter space.

[25] AAD 15BK search for production of a heavy H^0_2 decaying to H^0H^0 in the final state $b\overline{b}b\overline{b}$ in 19.5 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Figs. 15–18 for excluded regions in the parameter space.

[26] AAD 15S search for production of A^0 decaying to $ZH^0 \to \ell^+\ell^-b\overline{b}$, $\nu\overline{\nu}b\overline{b}$ and $\ell^+\ell^-\tau^+\tau^-$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Figs. 4 and 5 for excluded regions in the parameter space.

[27] KHACHATRYAN 15BB search for H^0_2, $A^0 \to \gamma\gamma$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 10 for excluded regions in the two-Higgs-doublet model parameter space.

[28] KHACHATRYAN 15N search for production of A^0 decaying to $ZH^0 \to \ell^+\ell^-b\overline{b}$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 5 for excluded regions in the $\tan\beta - \cos(\beta-\alpha)$ plane for m_{A^0} = 300 GeV.

[29] AAD 14M search for the decay cascade $H^0_2 \to H^\pm W^\mp \to H^0W^\pm W^\mp$, H^0 decaying to $b\overline{b}$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Table IV for limits in a two-Higgs-doublet model for $m_{H^0_2}$= 325–1025 GeV and m_{H^+}= 225–825 GeV.

[30] KHACHATRYAN 14Q search for $H^0_2 \to H^0H^0$ and $A^0 \to ZH^0$ in 19.5 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Figs. 4 and 5 for limits on cross section times branching ratio for m_{H_2,A^0}= 260–360 GeV and their Figs. 7–9 for limits in two-Higgs-doublet models.

[31] AALTONEN 09AR search for Higgs bosons decaying to $\tau^+\tau^-$ in two doublet models in 1.8 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. See their Fig. 2 for the limit on $\sigma\cdot$B($H^0_{1,2}/A^0 \to \tau^+\tau^-$) for different Higgs masses, and see their Fig. 3 for the excluded region in the MSSM parameter space.

[32] ABBIENDI 05A search for $e^+e^- \to H^0_1A^0$ in general Type-II two-doublet models, with decays H^0_1, $A^0 \to q\overline{q}$, gg, $\tau^+\tau^-$, and $H^0_1 \to A^0A^0$.

[33] ABDALLAH 05D search for $e^+e^- \to H^0Z$ and H^0A^0 with H^0, A^0 decaying to two jets of any flavor including gg. The limit is for SM H^0Z production cross section with B($H^0 \to jj$) = 1.

[34] ABDALLAH 04O search for $Z \to b\overline{b}H^0$, $b\overline{b}A^0$, $\tau^+\tau^-H^0$ and $\tau^+\tau^-A^0$ in the final states $4b$, $b\overline{b}\tau^+\tau^-$, and 4τ. See paper for limits on Yukawa couplings.

[35] ABDALLAH 04O search for $e^+e^- \to H^0Z$ and H^0A^0, with H^0, A^0 decaying to $b\overline{b}$, $\tau^+\tau^-$, or $H^0 \to A^0A^0$ at E_{cm} = 189–208 GeV. See paper for limits on couplings.

[36] ABBIENDI 02D search for $Z \to b\overline{b}H^0_1$ and $b\overline{b}A^0$ with $H^0_1/A^0 \to \tau^+\tau^-$, in the range $4 < m_H < 12$ GeV. See their Fig. 8 for limits on the Yukawa coupling.

[37] ABBIENDI 01E search for neutral Higgs bosons in general Type-II two-doublet models, at $E_{cm} \leq$ 189 GeV. In addition to usual final states, the decays H^0_1, $A^0 \to q\overline{q}$, gg are searched for. See their Figs. 15,16 for excluded regions.

[38] ABBIENDI 99E search for $e^+e^- \to H^0A^0$ and H^0Z at E_{cm} = 183 GeV. The limit is with m_H=m_A in general two Higgs-doublet models. See their Fig. 18 for the exclusion limit in the m_H-m_A plane. Updates the results of ACKERSTAFF 98S.

[39] See Fig. 4 of ABREU 95H for the excluded region in the $m_{H^0} - m_{A^0}$ plane for general two-doublet models. For $\tan\beta$ >1, the region $m_{H^0}+m_{A^0} \lesssim$ 87 GeV, m_{H^0} <47 GeV is excluded at 95% CL.

[40] PICH 92 analyse H^0 with $m_{H^0} < 2m_\mu$ in general two-doublet models. Excluded regions in the space of mass-mixing angles from LEP, beam dump, and $\pi^\pm$, η rare decays are shown in Figs. 3,4. The considered mass region is not totally excluded.

Mass Limits for H^0 with Vanishing Yukawa Couplings

These limits assume that H^0 couples to gauge bosons with the same strength as the Standard Model Higgs boson, but has no coupling to quarks and leptons (this is often referred to as "fermiophobic").

[1] AALTONEN 13K search for $H^0 \to WW^{(*)}$ in 9.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. A limit on cross section times branching ratio which corresponds to (1.3–6.6) times the expected cross section is given in the range m_{H^0} = 110–200 GeV at 95% CL.

[2] AALTONEN 13L combine all CDF searches with 9.45–10.0 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV.

[3] AALTONEN 13M combine all Tevatron data from the CDF and D0 Collaborations of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV.

[4] ABAZOV 13G search for $H^0 \to WW^{(*)}$ in 9.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. A limit on cross section times branching ratio which corresponds to (2–9) times the expected cross section is given for m_{H^0} = 100–200 GeV at 95% CL.

[5] ABAZOV 13H search for $H^0 \to \gamma\gamma$ in 9.6 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV.

[6] ABAZOV 13I search for H^0 production in the final state with one lepton and two or more jets plus missing E_T in 9.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The search is sensitive to WH^0, ZH^0 and vector-boson fusion Higgs production with $H^0 \to WW^{(*)}$. A limit on cross section times branching ratio which corresponds to (8–30) times the expected cross section is given in the range m_{H^0} = 100–200 GeV at 95% CL.

[7] ABAZOV 13J search for H^0 production in the final states $ee\mu$, $e\mu\mu$, $\mu\tau\tau$, and $e^\pm\mu^\pm$ in 8.6–9.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The search is sensitive to WH^0, ZH^0 production with $H^0 \to WW^{(*)}$, $ZZ^{(*)}$, decaying to leptonic final states. A limit on cross section times branching ratio which corresponds to (2.4–13.0) times the expected cross section is given in the range m_{H^0} = 100–200 GeV at 95% CL.

[8] ABAZOV 13L combine all D0 results with up to 9.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV.

[9] CHATRCHYAN 13AL search for $H^0 \to \gamma\gamma$ in 5.1 fb^{-1} and 5.3 fb^{-1} of pp collisions at E_{cm} = 7 and 8 TeV.

[10] AAD 12N search for $H^0 \to \gamma\gamma$ with 4.9 fb^{-1} of pp collisions at E_{cm} = 7 TeV in the mass range m_{H^0} = 110–150 GeV.

[11] AALTONEN 12AN search for $H^0 \to \gamma\gamma$ with 10 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV in the mass range m_{H^0} = 100–150 GeV.

[12] CHATRCHYAN 12AO use data from CHATRCHYAN 12G, CHATRCHYAN 12E, CHATRCHYAN 12H, CHATRCHYAN 12I, CHATRCHYAN 12D, and CHATRCHYAN 12C.

[13] AALTONEN 09AB search for $H^0 \to \gamma\gamma$ in 3.0 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV in the mass range m_{H^0} = 70–150 GeV. Associated H^0W, H^0Z production and WW, ZZ fusion are considered.

[14] ABAZOV 08U search for $H^0 \to \gamma\gamma$ in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV in the mass range m_{H^0} = 70–150 GeV. Associated H^0W, H^0Z production and WW, ZZ fusion are considered. See their Tab. 1 for the limit on $\sigma \cdot B(H^0 \to \gamma\gamma)$, and see their Fig. 3 for the excluded region in the m_{H^0} — $B(H^0 \to \gamma\gamma)$ plane.

[15] SCHAEL 07 search for Higgs bosons in association with a fermion pair and decaying to WW^*. The limit is from this search and HEISTER 02L for a H^0 with SM production cross section.

[16] Search for associated production of a $\gamma\gamma$ resonance with a Z boson, followed by $Z \to q\overline{q}$, $\ell^+\ell^-$, or $\nu\overline{\nu}$, at $E_{cm} \leq$ 209 GeV. The limit is for a H^0 with SM production cross section.

[17] Updates ABREU 01F.

[18] ACHARD 03C search for $e^+e^- \to ZH^0$ followed by $H^0 \to WW^*$ or ZZ^* at E_{cm}= 200-209 GeV and combine with the ACHARD 02C result. The limit is for a H^0 with SM production cross section. For $B(H^0 \to WW^*) + B(H^0 \to ZZ^*) = 1$, $m_{H^0} > 108.1$ GeV is obtained. See fig. 6 for the limits under different BR assumptions.

[19] For $B(H^0 \to \gamma\gamma)$=1, m_{H^0} >117 GeV is obtained.

[20] ACHARD 02C search for associated production of a $\gamma\gamma$ resonance with a Z boson, followed by $Z \to q\overline{q}$, $\ell^+\ell^-$, or $\nu\overline{\nu}$, at $E_{cm} \leq$ 209 GeV. The limit is for a H^0 with SM production cross section. For $B(H^0 \to \gamma\gamma)$=1, m_{H^0} >114 GeV is obtained.

[21] AFFOLDER 01H search for associated production of a $\gamma\gamma$ resonance and a W or Z (tagged by two jets, an isolated lepton, or missing E_T). The limit assumes Standard Model values for the production cross section and for the couplings of the H^0 to W and Z bosons. See their Fig. 11 for limits with $B(H^0 \to \gamma\gamma) < 1$.

[22] ACCIARRI 00S search for associated production of a $\gamma\gamma$ resonance with a $q\overline{q}$, $\nu\overline{\nu}$, or $\ell^+\ell^-$ pair in e^+e^- collisions at E_{cm}= 189 GeV. The limit is for a H^0 with SM production cross section. For $B(H^0 \to \gamma\gamma)$=1, $m_{H^0} > 98$ GeV is obtained. See their Fig. 5 for limits on $B(H \to \gamma\gamma)\cdot\sigma(e^+e^- \to Hf\overline{f})/\sigma(e^+e^- \to Hf\overline{f})$ (SM).

[23] BARATE 00L search for associated production of a $\gamma\gamma$ resonance with a $q\overline{q}$, $\nu\overline{\nu}$, or $\ell^+\ell^-$ pair in e^+e^- collisions at E_{cm}= 88–202 GeV. The limit is for a H^0 with SM production cross section. For $B(H^0 \to \gamma\gamma)$=1, $m_{H^0} > 109$ GeV is obtained. See their Fig. 3 for limits on $B(H \to \gamma\gamma)\cdot\sigma(e^+e^- \to Hf\overline{f})/\sigma(e^+e^- \to Hf\overline{f})$ (SM).

[24] ABBIENDI 99O search for associated production of a $\gamma\gamma$ resonance with a $q\overline{q}$, $\nu\overline{\nu}$, or $\ell^+\ell^-$ pair in e^+e^- collisions at 189 GeV. The limit is for a H^0 with SM production cross section. See their Fig. 4 for limits on $\sigma(e^+e^- \to H^0Z^0)\times B(H^0 \to \gamma\gamma)\times B(X^0 \to f\overline{f})$ for various masses. Updates the results of ACKERSTAFF 98Y.

[25] ABBOTT 99B search for associated production of a $\gamma\gamma$ resonance and a dijet pair. The limit assumes Standard Model values for the production cross section and for the couplings of the H^0 to W and Z bosons. Limits in the range of $\sigma(H^0 + Z/W)\cdot B(H^0 \to \gamma\gamma)$= 0.80–0.34 pb are obtained in the mass range m_{H^0}= 65–150 GeV.

[26] ABREU 99P search for $e^+e^- \to H^0\gamma$ with $H^0 \to b\overline{b}$ or $\gamma\gamma$, and $e^+e^- \to H^0q\overline{q}$ with $H^0 \to \gamma\gamma$. See their Fig. 4 for limits on $\sigma\times B$. Explicit limits within an effective interaction framework are also given.

Mass Limits for H^0 Decaying to Invisible Final States

These limits are for a neutral scalar H^0 which predominantly decays to invisible final states. Standard Model values are assumed for the couplings of H^0 to ordinary particles unless otherwise stated.

[1] AABOUD 19AI search for $H^0_{1,2}$ production by vector boson fusion and decay to invisible final states in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6(b) for limits on cross section times branching ratios for $m_{H^0_{1,2}}$ = 0.1–3 TeV.

[2] AAD 15BD search for $pp \to H^0WX$ and $pp \to H^0ZX$ with W or Z decaying hadronically and H^0 decaying to invisible final states in 20.3 fb^{-1} at E_{cm} = 8TeV. See their Fig. 6 for a limit on the cross section times branching ratio for m_{H^0} = 115–300 GeV.

[3] AAD 15BH search for events with a jet and missing E_T in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. Limits on $\sigma(H'^0)$ $B(H'^0 \to$ invisible) < (44–10) pb (95%CL) is given for $m_{H'^0}$ = 115–300 GeV.

[4] AAD 14BA search for H^0 production in the decay mode $H^0 \to X^0X^0$, where X^0 is a long-lived particle which decays to collimated pairs of e^+e^-, $\mu^+\mu^-$, or $\pi^+\pi^-$ plus invisible particles, in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Figs. 15 and 16 for limits on cross section times branching ratio.

[5] AAD 14O search for $pp \to H^0ZX$, $Z \to \ell\ell$, with H^0 decaying to invisible final states in 4.5 fb^{-1} at E_{cm} = 7 TeV and 20.3 fb^{-1} at E_{cm} = 8 TeV. See their Fig. 3 for a limit on the cross section times branching ratio for m_{H^0} = 110–400 GeV.

[6] CHATRCHYAN 14B search for $pp \to H^0ZX$, $Z \to \ell\ell$ and $Z \to b\overline{b}$, and also $pp \to qqH^0X$ with H^0 decaying to invisible final states using data at E_{cm} = 7 and 8 TeV. See their Figs. 10, 11 for limits on the cross section times branching ratio for m_{H^0} = 100–400 GeV.

[7] AAD 13AG search for H^0 production in the decay mode $H^0 \to X^0X^0$, where X^0 is a long-lived particle which decays to $\mu^+\mu^-X'^0$, in 1.9 fb^{-1} of pp collisions at E_{cm} = 7 TeV. See their Fig. 7 for limits on cross section times branching ratio.

[8] AAD 13AT search for H^0 production in the decay $H^0 \to X^0X^0$, where X^0 eventually decays to clusters of collimated e^+e^- pairs, in 2.04 fb^{-1} of pp collisions at E_{cm} = 7 TeV. See their Fig. 3 for limits on cross section times branching ratio.

[9] CHATRCHYAN 13BJ search for H^0 production in the decay chain $H^0 \to X^0X^0$, $X^0 \to \mu^+\mu^-X'^0$ in 5.3 fb^{-1} of pp collisions at E_{cm} = 7 TeV. See their Fig. 2 for limits on cross section times branching ratio.

[10] AAD 12AQ search for H^0 production in the decay mode $H^0 \to X^0X^0$, where X^0 is a long-lived particle which decays mainly to $b\overline{b}$ in the muon detector, in 1.94 fb^{-1} of pp collisions at E_{cm} = 7 TeV. See their Fig. 3 for limits on cross section times branching ratio for m_{H^0} = 120, 140 GeV, m_{X^0} = 20, 40 GeV in the $c\tau$ range of 0.5–35 m.

[11] AALTONEN 12AB search for H^0 production in the decay $H^0 \to X^0X^0$, where X^0 eventually decays to clusters of collimated $\ell^+\ell^-$ pairs, in 5.1 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. Cross section limits are provided for a benchmark MSSM model incorporating the parameters given in Table VI.

[12] AALTONEN 12U search for H^0 production in the decay mode $H^0 \to X^0X^0$, where X^0 is a long-lived particle with $c\tau \approx$ 1 cm which decays mainly to $b\overline{b}$, in 3.2 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. See their Figs. 9 and 10 for limits on cross section times branching ratio for m_{H^0} = (130–170) GeV, m_{X^0} = 20, 40 GeV.

[13] ABBIENDI 10 search for $e^+e^- \to H^0Z$ with H^0 decaying invisibly. The limit assumes SM production cross section and $B(H^0 \to$ invisible) = 1.

[14] ABBIENDI 07 search for $e^+e^- \to H^0Z$ with $Z \to q\overline{q}$ and H^0 decaying to invisible final states. The H^0 width is varied between 1 GeV and 3 TeV. A limit $\sigma \cdot B(H^0 \to$ invisible) < (0.07–0.57) pb (95%CL) is obtained at E_{cm} = 206 GeV for m_{H^0} = 60–114 GeV.

[15] Search for $e^+e^- \to H^0Z$ with H^0 decaying invisibly. The limit assumes SM production cross section and $B(H^0 \to$ invisible) = 1.

[16] ACCIARRI 00M search for $e^+e^- \to ZH^0$ with H^0 decaying invisibly at E_{cm}=183–189 GeV. The limit assumes SM production cross section and $B(H^0 \to$ invisible)=1. See their Fig. 6 for limits for smaller branching ratios.

Mass Limits for Light A^0

These limits are for a pseudoscalar A^0 in the mass range below $\mathcal{O}(10)$ GeV.

[1] ADACHI 23A search for flavor-changing τ decays $\tau \to eA^0$ and $\tau \to \mu A^0$, with A^0 invisible, using 62.8 fb^{-1} of e^+e^- collisions at E_{cm} = 10.58 GeV. Limits on B($\tau \to eA^0$)/B($\tau \to e\nu\nu$) in the range 1.1×10^{-3}–9.7×10^{-3} (95% CL) and B($\tau \to \mu A^0$)/B($\tau \to \mu\nu\nu$) in the range 0.7×10^{-3}–12.2×10^{-3} (95% CL) are given for m_{A^0} = 0–1.6 GeV. See their Fig. 2.

[2] TUMASYAN 23AR search for the decay $H \to A^0A^0$ with $A^0 \to \gamma\gamma$ (detected as a merged photonlike object) using 136 fb^{-1} of pp collisions at E_{cm} = 13 TeV. Limits on B($H \to A^0A^0$)·B^2($A^0 \to \gamma\gamma$) in the range 0.9×10^{-3}–3.3×10^{-3} (95% CL) are given for m_{A^0} = 0.1–1.2 GeV. See their Fig. 2.

[3] ABLIKIM 22H search for the process $J/\psi \to A^0\gamma$ with A^0 decaying to $\mu^+\mu^-$ in 9×10^9 J/ψ events and give limits on B($J/\psi \to A^0\gamma$)·B($A^0 \to \mu^+\mu^-$) in the range 1.2×10^{-9}–7.78×10^{-7} (90% CL) for 0.212 GeV $\le m_{A^0} \le$ 3.0 GeV. See their Fig. 4.

[4] JIA 22 search for the process $\Upsilon(2S) \to \Upsilon(1S)\pi^+\pi^- \to A^0\gamma\pi^+\pi^-$ with A^0 decaying to $\tau^+\tau^-$ or $\mu^+\mu^-$ in 158×10^6 $\Upsilon(2S)$ events and give limits on B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to \tau^+\tau^-$) in the range 3.8×10^{-6}–1.5×10^{-4} (90% CL) for m_{A^0} = 3.6–9.2 GeV, and B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to \mu^+\mu^-$) in the range 3.1×10^{-7}–1.6×10^{-5} (90% CL) for m_{A^0} = 0.21–9.2 GeV. See their Fig. 4.

[5] AAD 20AE search for the decay $H^0 \to ZA^0$, $Z \to \ell^+\ell^-$, A^0 decaying hadronically ($A^0 \to gg$ or $s\overline{s}$), in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. Limit on the product of production cross section and the $H^0 \to ZA^0$ branching ratio in the range 17–340 pb (95% CL) is given for m_{A^0} = 0.5–4.0 GeV, see their Table I.

[6] AABOUD 18AP search for the decay $H^0 \to A^0A^0 \to \mu^+\mu^-\mu^+\mu^-$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 10(b) for limits on B($H^0 \to A^0A^0$) in the range m_{A^0} = 1–2.5, 4.5–8 GeV, assuming a type-II two-doublet plus singlet model with tan(β) = 5.

[7] KHACHATRYAN 17AZ search for the decay $H^0 \to A^0A^0 \to \tau^+\tau^-\tau^+\tau^-$, $\mu^+\mu^-b\overline{b}$, and $\mu^+\mu^-\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Figs. 4, 5, and 6 for cross section limits in the range m_{A^0} = 5–62.5 GeV. See also their Figs. 7, 8, and 9 for interpretation of the data in terms of models with two Higgs doublets and a singlet.

[8] ABLIKIM 16E search for the process $J/\psi \to A^0\gamma$ with A^0 decaying to $\mu^+\mu^-$ and give limits on B($J/\psi \to A^0\gamma$)·B($A^0 \to \mu^+\mu^-$) in the range 2.8×10^{-8}–5.0×10^{-6} (90% CL) for 0.212 $\le m_{A^0} \le$ 3.0 GeV. See their Fig. 5.

[9] KHACHATRYAN 16F search for the decay $H^0 \to A^0A^0 \to \tau^+\tau^-\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 8 for cross section limits for m_{A^0} = 4–8 GeV.

[10] LEES 15H search for the process $\Upsilon(2S) \to \Upsilon(1S)\pi^+\pi^- \to A^0\gamma\pi^+\pi^-$ with A^0 decaying to $c\overline{c}$ and give limits on B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to c\overline{c}$) in the range 7.4×10^{-5}–2.4×10^{-3} (90% CL) for 4.00 $\le m_{A^0} \le$ 8.95 and 9.10 $\le m_{A^0} \le$ 9.25 GeV. See their Fig. 6.

[11] LEES 13C search for the process $\Upsilon(2S,3S) \to \Upsilon(1S)\pi^+\pi^- \to A^0\gamma\pi^+\pi^-$ with A^0 decaying to $\mu^+\mu^-$ and give limits on B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to \mu^+\mu^-$) in the range $(0.3–9.7)\times10^{-6}$ (90% CL) for 0.212 $\le m_{A^0} \le$ 9.20 GeV. See their Fig. 5(e) for limits on the $b-A^0$ Yukawa coupling derived by combining this result with AUBERT 09Z.

[12] LEES 13L search for the process $\Upsilon(2S) \to \Upsilon(1S)\pi^+\pi^- \to A^0\gamma\pi^+\pi^-$ with A^0 decaying to gg or $s\overline{s}$ and give limits on B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to gg$) between 1×10^{-6} and 2×10^{-2} (90% CL) for 0.5 $\le m_{A^0} \le$ 9.0 GeV, and B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to s\overline{s}$) between 4×10^{-6} and 1×10^{-3} (90%CL) for 1.5 $\le m_{A^0} \le$ 9.0 GeV. See their Fig. 4.

[13] LEES 13R search for the process $\Upsilon(2S) \to \Upsilon(1S)\pi^+\pi^- \to A^0\gamma\pi^+\pi^-$ with A^0 decaying to $\tau^+\tau^-$ and give limits on B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to \tau^+\tau^-$) in the range $0.9–13\times10^{-5}$ (90% CL) for 3.6 $\le m_{A^0} \le$ 9.2 GeV. See their Fig. 4 for limits on the $b-A^0$ Yukawa coupling derived by combining this result with AUBERT 09P.

[14] ABLIKIM 12 searches for the process $\psi(3686) \to \pi\pi J/\psi$, $J/\psi \to A^0\gamma$ with A^0 decaying to $\mu^+\mu^-$. It gives mass dependent limits on B($J/\psi \to A^0\gamma$)·B($A^0 \to \mu^+\mu^-$) in the range 4×10^{-7}–2.1×10^{-5} (90% C.L.) for 0.212 $\le m_{A^0} \le$ 3.0 GeV. See their Fig. 2.

[15] CHATRCHYAN 12V search for A^0 production in the decay $A^0 \to \mu^+\mu^-$ with 1.3 fb^{-1} of pp collisions at E_{cm} = 7 TeV. A limit on $\sigma(A^0)$·B($A^0 \to \mu^+\mu^-$) in the range (1.5–7.5) pb is given for m_{A^0} = (5.5–8.7) and (11.5–14) GeV at 95% CL.

[16] AALTONEN 11P search in 2.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV for the decay chain $t \to bH^+$, $H^+ \to W^+A^0$, $A^0 \to \tau^+\tau^-$ with m_{A^0} between 4 and 9 GeV. See their Fig. 4 for limits on B($t \to bH^+$) for $90 < m_{H^+} < 160$ GeV.

[17] ABOUZAID 11A search for the decay chain $K_L \to \pi^0\pi^0A^0$, $A^0 \to \mu^+\mu^-$ and give a limit B($K_L \to \pi^0\pi^0A^0$) · B($A^0 \to \mu^+\mu^-$) < 1.0×10^{-10} at 90% CL for m_{A^0} = 214.3 MeV.

[18] The search was motivated by PARK 05.

[19] DEL-AMO-SANCHEZ 11J search for the process $\Upsilon(2S) \to \Upsilon(1S)\pi^+\pi^- \to A^0\gamma\pi^+\pi^-$ with A^0 decaying to invisible final states. They give limits on B($\Upsilon(1S) \to A^0\gamma$)·B($A^0 \to$ invisible) in the range $(1.9–4.5)\times10^{-6}$ (90% CL) for 0 $\le m_{A^0} \le$ 8.0 GeV, and $(2.7–37)\times10^{-6}$ for 8.0 $\le m_{A^0} \le$ 9.2 GeV.

[20] LEES 11H search for the process $\Upsilon(2S,3S) \to A^0\gamma$ with A^0 decaying hadronically and give limits on B($\Upsilon(2S,3S) \to A^0\gamma$)·B($A^0 \to$ hadrons) in the range 1×10^{-6}–8×10^{-5} (90% CL) for 0.3 < m_{A^0} < 7 GeV. The decay rates for $\Upsilon(2S)$ and $\Upsilon(3S)$ are assumed to be equal up to the phase space factor. See their Fig. 5.

[21] ANDREAS 10 analyze constraints from rare decays and other processes on a light A^0 with $m_{A^0} < 2m_\mu$ and give limits on its coupling to fermions at the level of 10^{-4} times the Standard Model value.

[22] HYUN 10 search for the decay chain $B^0 \to K^{*0}A^0$, $A^0 \to \mu^+\mu^-$ and give a limit on B($B^0 \to K^{*0}A^0$) · B($A^0 \to \mu^+\mu^-$) in the range $(2.26–5.53)\times10^{-8}$ at 90%CL for m_{A^0} = 212–300 MeV. The limit for m_{A^0} = 214.3 MeV is 2.26×10^{-8}.

[23] HYUN 10 search for the decay chain $B^0 \to \rho^0A^0$, $A^0 \to \mu^+\mu^-$ and give a limit on B($B^0 \to \rho^0A^0$) · B($A^0 \to \mu^+\mu^-$) in the range $(1.73–4.51)\times10^{-8}$ at 90%CL for m_{A^0} = 212–300 MeV. The limit for m_{A^0} = 214.3 MeV is 1.73×10^{-8}.

[24] AUBERT 09P search for the process $\Upsilon(3S) \to A^0\gamma$ with $A^0 \to \tau^+\tau^-$ for 4.03 < m_{A^0} < 9.52 and 9.61 < m_{A^0} < 10.10 GeV, and give limits on B($\Upsilon(3S) \to A^0\gamma$)·B($A^0 \to \tau^+\tau^-$) in the range $(1.5–16)\times10^{-5}$ (90% CL).

[25] AUBERT 09Z search for the process $\Upsilon(2S) \to A^0\gamma$ with $A^0 \to \mu^+\mu^-$ for 0.212 < m_{A^0} < 9.3 GeV and give limits on B($\Upsilon(2S) \to A^0\gamma$)·B($A^0 \to \mu^+\mu^-$) in the range $(0.3–8)\times10^{-6}$ (90% CL).

[26] AUBERT 09Z search for the process $\Upsilon(3S) \to A^0\gamma$ with $A^0 \to \mu^+\mu^-$ for 0.212 < m_{A^0} < 9.3 GeV and give limits on B($\Upsilon(3S) \to A^0\gamma$)·B($A^0 \to \mu^+\mu^-$) in the range $(0.3–5)\times10^{-6}$ (90% CL).

[27] TUNG 09 search for the decay chain $K_L \to \pi^0\pi^0A^0$, $A^0 \to \gamma\gamma$ and give a limit on B($K_L \to \pi^0\pi^0A^0$) · B($A^0 \to \gamma\gamma$) in the range $(2.4–10.7)\times10^{-7}$ at 90%CL for m_{A^0} = 194.3–219.3 MeV. The limit for m_{A^0} = 214.3 MeV is 2.4×10^{-7}.

[28] LOVE 08 search for the process $\Upsilon(1S) \to A^0\gamma$ with $A^0 \to \mu^+\mu^-$ (for $m_{A^0} < 2m_\tau$) and $A^0 \to \tau^+\tau^-$. Limits on B($\Upsilon(1S) \to A^0\gamma$) · B($A^0 \to \ell^+\ell^-$) in the range 10^{-6}–10^{-4} (90% CL) are given.

[29] BESSON 07 give a limit B($\Upsilon(1S) \to \eta_b\gamma$) · B($\eta_b \to \tau^+\tau^-$) < 0.27% (95% CL), which constrains a possible A^0 exchange contribution to the η_b decay.

[30] PARK 05 found three candidate events for $\Sigma^+ \to p\mu^+\mu^-$ in the HyperCP experiment. Due to a narrow spread in dimuon mass, they hypothesize the events as a possible signal of a new boson. It can be interpreted as a neutral particle with $m_{A^0} = 214.3 \pm 0.5$ MeV and the branching fraction B($\Sigma^+ \to pA^0$)·B($A^0 \to \mu^+\mu^-$) = $(3.1^{+2.4}_{-1.9}\pm1.5)\times10^{-8}$.

[31] BALEST 95 give limits B($\Upsilon(1S) \to A^0\gamma$) ¡ 1.5×10^{-5} at 90% CL for m_{A^0} < 5 GeV. The limit becomes < 10^{-4} for m_{A^0} < 7.7 GeV.

[32] ANTREASYAN 90C give limits B($\Upsilon(1S) \to A^0\gamma$) ¡ 5.6×10^{-5} at 90% CL for m_{A^0} < 7.2 GeV. A^0 is assumed not to decay in the detector.

Other Mass Limits

We use a symbol H^0_1 if mass < 125 GeV or H^0_2 if mass > 125 GeV. The notation H is reserved for the 125 GeV particle.

[1] AAD 24A search for the decay $H_2^0 \to Z\gamma$ with Z decaying to e^+e^- or $\mu^+\mu^-$ using 140 fb^{-1} of pp collisions at $E_{\rm cm}$ = 13 TeV. See their Fig. 4 for limits on production cross section times branching ratios for $m_{H_2^0}$ = 0.22–3.4 TeV.

[2] AAD 23AD search for associated production of W/ZH_2^0 with the decay chain $H_2^0 \to HH \to b\overline{b}b\overline{b}$ using 139 fb^{-1} of pp collisions at $E_{\rm cm}$ = 13 TeV. See their Fig. 9 for limits on cross section times branching ratios for $m_{H_2^0}$ = 260–1000 GeV.

[3] AAD 23AD search for gluon fusion production of A^0 with the decay chain $A^0 \to ZH^0_2$, $H^0_2 \to HH \to b\overline{b}b\overline{b}$ using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 10 for limits on cross section times branching ratios for m_{A^0} = 350–800 GeV and $m_{H^0_2}$ = 260–400 GeV.

[4] AAD 23AJ search for production of $H^\pm$ in association with a top quark, followed by $H^\pm \to W^\pm A^0$, $A^0 \to$ invisible, using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 10 for excluded parameter regions of 2HDM + CP-odd singlet model.

[5] AAD 23BD search for a top quark decaying to $qH^0_{1,2}$ ($q = u, c$), $H^0_{1,2} \to b\overline{b}$, using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 9 for limits on production cross section times branching ratios for $m_{H^0_{1,2}}$ = 20–160 GeV.

[6] AAD 23BE search for associated production of $H^0_2 W$ and decay $H^0_2 \to W^+W^-$ assuming the presence of higher dimensional $H^0_2 W^+W^-$ interactions, using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6 for excluded parameter region of higher dimensional operators, and Fig. 7 for limits on cross section times branching ratio for $m_{H^0_2}$ = 0.3–1.5 TeV.

[7] AAD 23BG search for production of H^0_2/A^0 in association with a $t\overline{t}$ pair, decaying to $t\overline{t}$, using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 7 for limits on cross section times branching ratios for $m_{H^0_2} = m_{A^0}$ = 0.4–1.0 TeV.

[8] AAD 23BW search for A^0 production in association with a $t\overline{t}$ pair, decaying to $\mu^+\mu^-$, using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5(a) for limits on production cross section times branching ratio for m_{A^0} = 15–72 GeV.

[9] AAD 23BX search for production of $H \to \tau^+\tau^-$ with missing transverse momentum using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 8 for interpretation of the data in terms of 2HDM + a model.

[10] AAD 23CA search for production of H^0_3 decaying to $H^0_2 H$, $H^0_2 \to W^+W^-$ or ZZ, and $H \to \tau^+\tau^-$ using 140 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 4, 5 for limits on production cross section times branching ratios in the ranges $m_{H^0_3}$ = 0.5–1.5 TeV and $m_{H^0_2}$ = 0.2–0.5 TeV.

[11] AAD 23CR search for H^0_2 having flavor-violating couplings to tc or tu, produced in association with top quark(s), using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 14 for limits on production cross section times branching ratios for $m_{H^0_2}$ = 0.2–1.5 TeV with various assumptions on the flavor-changing couplings.

[12] AAD 23O search for production of an A^0 in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to ZH in the final states $\nu\overline{\nu}b\overline{b}$ and $\ell^+\ell^- b\overline{b}$ using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 9 for limits on cross section times branching ratio for m_{A^0} = 0.22–2.0 TeV, and Fig. 11 for limits with both production components.

[13] AAD 23R search for the decay $A^0 \to \gamma\gamma$ in 138 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 7 for limits on cross section times branching ratio for m_{A^0} = 10–70 GeV.

[14] AAD 23U search for the decay $H^0_2 \to Z\gamma$ with Z decaying hadronically in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 8(a) for limits on production cross section times branching ratios for $m_{H^0_2}$ = 1.0–6.8 TeV.

[15] AAD 23Z search for the decay chain $H^0_2 \to HH \to b\overline{b}\tau^+\tau^-$ using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 10 for limits on the product of production cross section times branching ratios for $m_{H^0_2}$ = 0.251–1.6 TeV.

[16] HAYRAPETYAN 23C search for $H^0_{1,2} \to e\mu$ using 138 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 7 for limits on production cross section times branching ratio for $m_{H^0_{1,2}}$ = 110–160 GeV.

[17] HAYRAPETYAN 23G search for dimuon resonance in the mass range 1.1–2.6 or 4.2–7.9 GeV in 96.6 fb^{-1} of pp collisions at E_{cm} = 13 TeV, in inclusive and high p_T selections. See their Fig. 5 for cross section times branching ratio limits and Fig. 7 for mixing angle limits in two Higgs doublet plus singlet model (at 90% CL).

[18] TUMASYAN 23 search for production of H^0_3 decaying to $H^0_{1,2}H \to b\overline{b}b\overline{b}$ using 138 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 4 for limits on production cross section times branching ratios for $m_{H^0_3}$ = 0.9–4.0 TeV and $m_{H^0_{1,2}}$ = 60–600 GeV, and their interpretation in the NMSSM and the Two Real Singlet Model (TRSM).

[19] TUMASYAN 23M search for the decay chain $H \to A^0A^0 \to \gamma\gamma\gamma\gamma$ in 132 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6 for limits on cross section times branching ratio in the range m_{A^0} = 15–62 GeV.

[20] TUMASYAN 23O search for $H^0_2 \to HH$, each H decaying to either WW^* or $\tau^+\tau^-$ using 138 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 14 (upper) for limit on the product of production cross section times branching ratios for $m_{H^0_2}$ = 0.25–1.0 TeV.

[21] TUMASYAN 23S search for gluon fusion and b-associated production of $H^0_{1,2}$ decaying to $\tau^+\tau^-$ using 138 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 10 for limits on production cross section times branching ratios for $m_{H^0_{1,2}}$ = 0.06–3.5 TeV.

[22] AAD 22A search for the decay chain $H \to A^0A^0 \to \mu^+\mu^- b\overline{b}$ in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 9 for limits on the overall branching fraction in the range m_{A^0} = 16–62 GeV. See also Fig. 11 for limits without assuming A^0 is pseudoscalar.

[23] AAD 22D search for ZA^0 associate production with $Z \to \ell^+\ell^-$, A^0 decaying invisibly, in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5 for excluded regions in the mass parameter space of two Higgs doublet plus singlet (2HDM+A^0) model with a certain choice of the model parameters.

[24] AAD 22F search for gluon fusion production of H^0_2 decaying to $HH \to b\overline{b}b\overline{b}$ using 126–139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. B($H \to b\overline{b}$) = 0.582 is assumed. See their Fig. 14 for limit on the product of production cross section times branching ratios for $m_{H^0_2}$ = 0.251–5.0 TeV.

[25] AAD 22I search for ZH associate production with the decay chain $H \to \tilde{\chi}^0_2\tilde{\chi}^0_1$, $\tilde{\chi}^0_2 \to A^0\tilde{\chi}^0_1$, $A^0 \to b\overline{b}$, and $Z \to \ell^+\ell^-$, in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 3 and 4 for limits on the product of cross section times the branching ratios for m_{A^0} = 20–65 GeV with various choices of NMSSM model parameters.

[26] AAD 22J search for the decay $H \to ZA^0$ with $A^0 \to \mu^+\mu^-$ and $Z \to e^+e^-$, $\mu^+\mu^-$ in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV assuming SM gluon-gluon fusion production of the H. See their Fig. 17(b) for limits on the product of cross section times the branching ratios for m_{A^0} = 15–30 GeV.

[27] AAD 22J search for the decay $H \to A^0A^0$ with $A^0 \to \mu^+\mu^-$ in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV assuming SM gluon-gluon fusion production of the H in the range of m_{A^0} = 1–60 GeV . See their Fig. 14(b) for limits on the product of cross section times the branching ratios for m_{A^0} = 1.5–60 GeV (excluding ψ and Υ regions). The limit also applies to the decay $H \to H^0_1H^0_1$.

[28] AAD 22P search for invisibly decaying H^0_1, H^0_2 produced by vector boson fusion in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. Limit on the product of cross section times branching ratio in the range 0.1–1 pb (95% CL) is given for the mass range 0.05–2 TeV. See their Fig. 14.

[29] AAD 22Y search for gluon fusion production of H^0_2 decaying to $HH \to b\overline{b}\gamma\gamma$ in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 15 for limit on the product of production cross section times branching ratios to HH for $m_{H^0_2}$ = 0.251–1.0 TeV.

[30] ABRATENKO 22A search for a singlet scalar boson H^0_1 having a small mixing with the SM Higgs boson in the decay chain $K^+ \to H^0_1\pi^+$, $H^0_1 \to \mu^+\mu^-$ from data corresponding to 7.01×10^{20} protons on NuMI target. See their Fig. 13 (right) and Table V for limits on the SM Higgs component of H^0_1 for $m_{H^0_1}$ = 212–279 MeV.

[31] TUMASYAN 22AK search for gluon-fusion production of H^0_3 decaying to $H^0_1H^0_1 \to b\overline{b}b\overline{b}$ in 138 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5 for limits on cross section times branching ratio for $m_{H^0_3}$ = 1–3 TeV, $m_{H^0_1}$ = 25–100 GeV.

[32] TUMASYAN 22D search for production of an H^0_2 (denoted radion in the paper) in gluon fusion and vector boson fusion, decaying to W^+W^- in the final states $\ell\nu$ + hadrons, using 137 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 7 for limits on cross section times branching ratio for $m_{H^0_2}$ = 1.0–4.5 TeV.

[33] AAD 21AF search for production of a heavy H^0_2 state decaying to ZZ in the final states $\ell^+\ell^-\ell'^+\ell'^-$ and $\ell^+\ell^-\nu\overline{\nu}$ in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 4 for upper limits on cross section times branching ratio for $m_{H^0_2}$ = 0.2–2.0 TeV assuming ggF or VBF with narrow width approximation, and Fig. 5 for upper limits on cross section times branching ratio for $m_{H^0_2}$ = 0.4–2.0 TeV assuming ggF, and with several assumptions on its width.

[34] AAD 21AI search for production of an A^0 in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to $ZH^0_2 \to \ell^+\ell^- b\overline{b}$ or $\ell^+\ell^- W^+W^-$ in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 9 and 13 for cross section limits for m_{A^0} = 230–800 GeV and $m_{H^0_2}$ = 130–700 GeV.

[35] AAD 21AY search for production of a scalar resonance decaying to $\gamma\gamma$ in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5(a) for limits on fiducial cross section times branching ratio for $m_{H^0_2}$ = 0.16–3 TeV with narrow width approximation, and Table 2 with several assumptions on the width.

[36] AAD 21AZ search for production of A^0_2 decaying to HA^0_1 followed by $H \to \gamma\gamma$, $A^0_1 \to$ invisible in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 10–12 for limits in terms of two-Higgs-doublet model plus singlet pseudoscalar and a fermionic Dark Matter particle.

[37] AAD 21BB search for production of A^0_2 by gluon fusion or associated $A^0_2 b\overline{b}$ production, decaying to HA^0_1 followed by $H \to b\overline{b}$, $A^0_1 \to$ invisible in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 8 for limits in terms of two-Higgs-doublet plus singlet pseudoscalar model.

[38] AAD 21BE search for production of A^0_1 associated with a single top quark and either a light quark or a W boson, decaying to invisible final states, in 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 13–15 for limits in terms of two-Higgs-doublet model plus singlet pseudoscalar, which is assumed to decay to a pair of Dark Matter particles.

[39] ABRATENKO 21 search for a singlet scalar boson H^0_1 having a small mixing with the SM Higgs boson in the decay chain $K^+ \to H^0_1\pi^+$, $H^0_1 \to e^+e^-$ from data corresponding to 1.93×10^{20} protons on NuMI target. See their Fig. 2 for limits on the SM Higgs component of H^0_1 for $m_{H^0_1}$ = 3–210 MeV.

[40] SIRUNYAN 21A search for $H^0_2 \to ZA^0$ with $Z \to \ell^+\ell^-$, A^0 decaying invisibly, in 137 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 8 for excluded regions in the mass parameter space of two Higgs doublet plus singlet model with a certain choice of the model parameters.

[41] TUMASYAN 21F search for gluon fusion production of H^0_3 decaying to $HH^0_{1,2} \to \tau^+\tau^- b\overline{b}$ in 137 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 5 and 6 for limits on cross section times branching ratios for $m_{H^0_{1,2}}$ = 0.06–2.8 TeV and $m_{H^0_3}$ = 0.24–3.0 TeV.

[42] AAD 20AA search for $H^0_2/A^0 \to \tau^+\tau^-$ produced by gluon fusion or b-associated production using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 2(a), 2(b) for limits on the product of cross section and branching ratio for $m_{H^0_2}$, m_{A^0} = 0.2–2.5 TeV.

[43] AAD 20AI search for ZH production followed by the decay $H \to A^0A^0 \to b\overline{b}b\overline{b}$ in 36 fb^{-1} of pp collisions at E_{cm} = 13 TeV. The search looks for collimated $A^0 \to b\overline{b}$ decays and is complementary to AABOUD 18BX. See their Fig. 10 for limits on the product of production cross section and branching ratios in the range m_{A^0} = 15–30 GeV.

[44] AAD 20AO search for gluon fusion production of H_2^0 decaying to $HH \to \tau^+\tau^- b\overline{b}$ (with hadronically decaying $\tau^+\tau^-$) using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. Limit on the product of production cross section times branching ratios in the range 28–817 fb (95% CL) is given for m_{A^0} = 1.0–3.0 TeV, see their Fig. 13.

[45] AAD 20C combine searches for a scalar resonance decaying to HH in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV from AABOUD 19A, AABOUD 19O, AABOUD 18CQ, AABOUD 19T, AABOUD 18CW, and AABOUD 18BU. See their Fig. 5(a) for limits on cross section times branching ratio for $m_{H_2^0}$ = 0.26–3 TeV.

[46] AAD 20L search for b-associated production of H_2^0 decaying to $b\overline{b}$ in 27.8 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 8 for limits on the product of cross section and branching ratio for $m_{H_2^0}$ = 0.45–1.4 TeV.

[47] AAD 20X search for vector-boson-fusion production of H_2^0 decaying to HH using 126 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5 for limits on the product of cross section and branching ratio for the assumptions of a narrow- and broad-width resonance.

[48] AAIJ 20AL search for dimuon resonance in the mass range 0.2–60 GeV in 5.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV, in inclusive and b quark associated production. Displaced decays are searched for for masses below 3 GeV. See their Figs. 7–9 for cross section limits and Fig. 10 for limits for mixing angle in two Higgs doublet plus singlet model (at 90% CL).

[49] SIRUNYAN 20 search for the decay $H \to A^0A^0 \to \tau^+\tau^-\tau^+\tau^-$ or $\tau^+\tau^-\mu^+\mu^-$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 10 for limits on the product of production cross section (normalized to the SM) and branching ratios in the range m_{A^0} = 4–15 GeV.

[50] SIRUNYAN 20AA search for $H_2^0 \to ZA^0$, $A^0 \to b\overline{b}$ or $A^0 \to ZH_2^0$, $H_2^0 \to b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 7 for limits on the product of cross section and branching ratio for $m_{H_2^0}$ = 0.12–1 TeV and m_{A^0} = 0.03–1 TeV.

[51] SIRUNYAN 20AC search for gluon-fusion production of A^0 decaying to ZH in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5 for limits on the product of cross section and branching ratios for m_{A^0} = 220–400 GeV.

[52] SIRUNYAN 20AD search for lepton-flavor violating decays $H_2^0 \to \mu\tau$, $e\tau$ of gluon-fusion-produced H_2^0 in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5 (9) and Table 5 (6) for limits on production cross section times branching ratio for $m_{H_2^0}$ = 0.2–0.9 TeV for the $\mu\tau$ ($e\tau$) final state.

[53] SIRUNYAN 20AF search for $H_2^0/A^0 \to t\overline{t}$ with one or two charged leptons in the final state using kinematic variables in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 5 and 6 for limits on top Yukawa coupling of H_2^0 and A^0 for $m_{H_2^0}$, m_{A^0} = 0.4–0.75 TeV for various width assumptions.

[54] SIRUNYAN 20AP search for the decay H or $H_2^0 \to A^0A^0 \to \mu^+\mu^-\tau^+\tau^-$ (for $m_{H_2^0}$ = 300 GeV) with boosted final-state topology in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 7 for limits on the product of production cross section (normalized to the SM) and branching ratios in the range m_{A^0} = 3.6–21 GeV, and Figs. 8 and 9 for its interpretation in terms of models with two Higgs doublets plus a singlet.

[55] SIRUNYAN 20Y search for gluon-fusion and vector-boson-fusion production of H_2^0 decaying to W^+W^- in the final states $\ell\nu\ell\nu$ and $\ell\nu qq$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6 for limits on the product of cross section and branching ratio for $m_{H_2^0}$ = 0.2–3 TeV.

[56] SIRUNYAN 20Z search for $H_{1,2}^0$ or A^0 production in association with a $t\overline{t}$ pair, decaying to e^+e^- or $\mu^+\mu^-$, in 137 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 12 for limits on production cross section times branching ratio for $m_{H_{1,2}^0}$, m_{A^0} = 15–75 GeV and 108–340 GeV.

[57] AABOUD 19A search for a narrow scalar resonance decaying to $HH \to b\overline{b}b\overline{b}$ in 27.5–36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 9(a) for limits on cross section times branching ratios for $m_{H_2^0}$ = 0.26–3 TeV.

[58] AABOUD 19AG search for the decay $H \to A^0A^0 \to \mu^+\mu^- b\overline{b}$ in 36.7 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6 (a) for limits on the product of production cross section (normalized to the SM) and branching ratios in the range m_{A^0} = 20–60 GeV.

[59] AABOUD 19O search for a scalar resonance decaying to $HH \to b\overline{b}WW^*$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 12 (left) for limits on cross section times branching ratio for $m_{H_2^0}$ = 0.5–3 TeV.

[60] AABOUD 19T search for a scalar resonance decaying to $HH \to WW^*WW^*$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 3 for limits on cross section times branching ratio for $m_{H_2^0}$ = 260–500 GeV, assuming SM decay rates for the H.

[61] AABOUD 19V combine published ATLAS data to constrain two-Higgs-doublet plus singlet pseudoscalar model with A_1^0 decaying to invisible final states. See their Fig. 19 for excluded parameter regions.

[62] AABOUD 19Y search for a narrow scalar resonance produced by gluon fusion or b associated production, decaying to $\mu^+\mu^-$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 4 and 5(a) for cross section limits for $m_{H_2^0}$ = 0.2–1.0 TeV.

[63] AALTONEN 19 search for b associated production of a scalar particle decaying to $b\overline{b}$ in 5.4 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. See their Fig. 3 for limits on cross section times branching ratio for $m_{H_{1,2}^0}$ = 100–300 GeV.

[64] SIRUNYAN 19 search for a narrow scalar resonance decaying to $HH \to \gamma\gamma b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 9 (left) for limits on cross section times branching ratios for $m_{H_2^0}$ = 260–900 GeV.

[65] SIRUNYAN 19AE search for a scalar resonance produced in association with a $b\overline{b}$ pair, decaying to $\tau^+\tau^-$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 4 for cross section limits for m_{A^0} = 25–70 GeV.

[66] SIRUNYAN 19AN search for production of A_2^0 decaying to HA_1^0 followed by $H \to b\overline{b}$, $A_1^0 \to$ invisible in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV, in the mass range $m_{A_2^0}$ = 0.2–1.6 TeV, $m_{A_1^0}$ = 0.15–0.5 TeV. See their Fig. 6 for limits in terms of two-Higgs-doublet plus singlet pseudoscalar model.

[67] SIRUNYAN 19AV search for a scalar resonance produced by gluon fusion or b-associated production, decaying to $ZH \to \ell^+\ell^- b\overline{b}$ ($\ell = e$, μ) or $\nu\overline{\nu}b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5 for cross section limits for m_{A^0} = 0.22–1.0 TeV.

[68] SIRUNYAN 19B search for gluon fusion production of narrow scalar resonance with large transverse momentum, decaying to $b\overline{b}$, in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 7 and 8 for limits on cross section times branching ratio for the resonance mass of 50–350 GeV.

[69] SIRUNYAN 19BB search for the decay $H_1^0 \to \gamma\gamma$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV and 35.9 fb^{-1} at E_{cm} = 13 TeV. See their Figs. 4–6 for limits on cross section times branching ratio for $m_{H_1^0}$ = 80–110 GeV (some results in Fig. 5 for $m_{H_1^0}$ = 70–110 GeV).

[70] SIRUNYAN 19BD search for the decay $H \to A^0A^0 \to \mu^+\mu^- b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5 for limits on the product of cross section times branching ratios in the range m_{A^0} = 20–62.5 GeV. See also their Figs. 6 and 7 for interpretation of the data in terms of models with two Higgs doublets and a singlet.

[71] SIRUNYAN 19BE combine searches for $H_2^0 \to HH$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV in various H decay modes, from SIRUNYAN 18A, SIRUNYAN 18AF, SIRUNYAN 18CW, SIRUNYAN 19, and SIRUNYAN 19H. See their Fig. 3 for limits on cross section times branching ratios for $m_{H_2^0}$ = 0.25–3 TeV.

[72] SIRUNYAN 19BQ search for production of $H_{1,2}^0$ decaying to $A^0A^0 \to \mu^+\mu^-\mu^+\mu^-$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 2 for limits on cross section times branching ratio for $m_{H_{1,2}^0}$ = 90–150 GeV, m_{A^0} = 0.25–3.55 GeV.

[73] SIRUNYAN 19CR search for production of H_2^0/A^0 in gluon fusion and in association with a $b\overline{b}$ pair, decaying to $\mu^+\mu^-$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6 for limits on cross section times branching ratio.

[74] SIRUNYAN 19H search for a narrow scalar resonance decaying to $HH \to b\overline{b}b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV, where one $b\overline{b}$ pair is resolved and the other not. Limits on cross section times branching ratios for $m_{H_2^0}$ = 0.75–1.6 TeV are obtained and combined with data from SIRUNYAN 18AF. See their Fig. 5 (right).

[75] AABOUD 18AA search for production of a scalar resonance decaying to $Z\gamma$, with Z decaying hadronically, in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 8(a) for limits on cross section times branching ratio for $m_{H_2^0}$ = 1.0–6.8 TeV.

[76] AABOUD 18AG search for the decay $H \to A^0A^0 \to \gamma\gamma gg$ in 36.7 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 2 and Table 6 for cross section limits in the range m_{A^0} = 20–60 GeV.

[77] AABOUD 18AH search for production of an A^0 in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to $ZH_2^0 \to \ell^+\ell^- b\overline{b}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5 for cross section limits for m_{A^0} = 230–800 GeV and $m_{H_2^0}$ = 130–700 GeV.

[78] AABOUD 18AI search for production of an A^0 in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to ZH in the final states $\nu\overline{\nu}b\overline{b}$ and $\ell^+\ell^- b\overline{b}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6 for cross section limits for m_{A^0} = 0.2–2 TeV. See also AABOUD 18CC.

[79] AABOUD 18BF search for production of a heavy H_2^0 state decaying to ZZ in the final states $\ell^+\ell^-\ell^+\ell^-$ and $\ell^+\ell^-\nu\overline{\nu}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 6 for upper limits on cross section times branching ratio for $m_{H_2^0}$ = 0.2–1.2 TeV assuming ggF or VBF with the NWA. See their Fig. 7 for upper limits on cross section times branching ratio for $m_{H_2^0}$ = 0.4–1.0 TeV assuming ggF, and with several assumptions on its width.

[80] AABOUD 18BU search for a narrow scalar resonance decaying to $HH \to \gamma\gamma WW^*$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 4 for limits on cross section times branching ratios for $m_{H_2^0}$ = 260–500 GeV.

[81] AABOUD 18BX search for associated production of WH or ZH followed by the decay $H \to A^0A^0 \to b\overline{b}b\overline{b}$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 9 for limits on cross section times branching ratios for m_{A^0} = 20–60 GeV. See also their Fig. 10 for the dependence of the limit on A^0 lifetime.

[82] AABOUD 18CQ search for a narrow scalar resonance decaying to $HH \to b\overline{b}\tau^+\tau^-$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 2 (above) for limits on cross section times branching ratios for $m_{H_2^0}$ = 260–1000 GeV.

[83] AABOUD 18F search for production of a narrow scalar resonance decaying to W^+W^- and ZZ, followed by hadronic decays of W and Z, in 36.7 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 5(c) for limits on cross section times branching ratio for $m_{H_2^0}$ = 1.2–3.0 TeV.

[84] AAIJ 18AM search for gluon-fusion production of $H_{1,2}^0$ decaying to $\mu\tau$ in 2 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 2 for limits on cross section times branching ratio for $m_{H_{1,2}^0}$ = 45–195 GeV.

[85] AAIJ 18AQ search for gluon-fusion production of a scalar particle A^0 decaying to $\mu^+\mu^-$ in 1.99 fb^{-1} of pp collisions at E_{cm} = 8 TeV and 0.98 fb^{-1} at E_{cm} = 7 TeV. See their Fig. 4 for limits on cross section times branching ratio for m_{A^0} = 5.5–15 GeV (using the E_{cm} = 8 TeV data set).

[86] AAIJ 18AQ search for the decay $H \to A^0A^0$, with one of the A^0 decaying to $\mu^+\mu^-$, in 1.99 fb^{-1} of pp collisions at E_{cm} = 8 TeV and 0.98 fb^{-1} at E_{cm} = 7 TeV. See their Fig. 5 (right) for limits on the product of branching ratios for m_{A^0} = 5.5–15 GeV (using the E_{cm} = 8 TeV data set).

[87] SIRUNYAN 18AF search for a narrow scalar resonance decaying to $HH \to b\overline{b}b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV, where both $b\overline{b}$ pairs are not resolved. See their Fig. 9 for limits on cross section times branching ratios for $m_{H_2^0}$ = 0.75–3 TeV.

[88] SIRUNYAN 18BA search for production of a heavy H_2^0 state decaying to ZZ in the final states $\ell^+\ell^-\ell^+\ell^-$, $\ell^+\ell^-q\overline{q}$, and $\ell^+\ell^-\nu\overline{\nu}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Figs. 10 and 11 for upper limits on cross section times branching ratio for $m_{H_2^0}$ = 0.13–3 TeV with several assumptions on its width and on the fraction of Vector-Boson-Fusion of the total production cross section.

[89] SIRUNYAN 18CW search for a narrow scalar resonance decaying to $HH \to b\overline{b}b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV, where both $b\overline{b}$ pairs are resolved. See their Fig. 9 for limits on cross section times branching ratios for $m_{H_2^0}$ = 260–1200 GeV.

[90] SIRUNYAN 18DK search for production of a scalar resonance decaying to $Z\gamma$, with Z decaying to $\ell^+\ell^-$ or hadronically, in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 7 for limits on cross section times branching ratio for $m_{H_2^0}$ = 0.35–4 TeV for different assumptions on the width of the resonance.

[91] SIRUNYAN 18DT search for the decay $H \to A^0A^0 \to \tau^+\tau^-b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 7 for limits on the product of branching ratios in the range m_{A^0} = 15–60 GeV. See also their Fig. 8 for interpretation of the data in terms of models with two Higgs doublets and a singlet.

[92] SIRUNYAN 18DU search for production of a narrow scalar resonance decaying to $\gamma\gamma$ in 35.9 fb^{-1} (taken in 2016) of pp collisions at E_{cm} = 13 TeV. See their Fig. 3 (right) for limits on cross section times branching ratio for $m_{H_2^0}$ = 0.5–5 TeV for several values of its width-to-mass ratio.

[93] SIRUNYAN 18ED search for production of an A^0 in gluon-gluon fusion and in association with a $b\overline{b}$, decaying to ZH in the final states $\nu\overline{\nu}b\overline{b}$ or $\ell^+\ell^-b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 8 for cross section limits for m_{A^0} = 0.8–2 TeV.

[94] SIRUNYAN 18EE search for the decay $H \to A^0A^0 \to \mu^+\mu^-\tau^+\tau^-$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 4 for limits on the product of branching ratios in the range m_{A^0} = 15–62.5 GeV, normalized to the SM production cross section. See also their Fig. 5 for interpretation of the data in terms of models with two Higgs doublets and a singlet.

[95] SIRUNYAN 18F search for a narrow scalar resonance decaying to $HH \to WWb\overline{b}$ or $ZZb\overline{b}$ in the final state $\ell\ell\nu\nu b\overline{b}$ in 35.9 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 7 for limits on cross section times branching ratios for $m_{H_2^0}$ = 250–900 GeV.

[96] AABOUD 17 search for production of a scalar resonance decaying to $Z\gamma$ in 3.2 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 4 for the limits on cross section times branching ratio for $m_{H_2^0}$ = 0.25–3.0 TeV.

[97] AABOUD 17AP search for production of a scalar resonance decaying to $\gamma\gamma$ in 36.7 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 4(a) for limits on fiducial cross section times branching ratio for $m_{H_2^0}$ = 0.2–2.7 TeV with narrow width approximation.

[98] AABOUD 17AW search for production of a scalar resonance decaying to $Z\gamma$ in 36.1 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 7 for limits on cross section times branching ratio for $m_{H_2^0}$ = 0.25–2.4 TeV.

[99] KHACHATRYAN 17AZ search for the decay $H \to A^0A^0 \to \tau^+\tau^-\tau^+\tau^-$, $\mu^+\mu^-b\overline{b}$, and $\mu^+\mu^-\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Figs. 4, 5, and 6 for cross section limits in the range m_{A^0} = 5–62.5 GeV. See also their Figs. 7, 8, and 9 for interpretation of the data in terms of models with two Higgs doublets and a singlet.

[100] KHACHATRYAN 17D search for production of a scalar resonance decaying to $Z\gamma$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV and 2.7 fb^{-1} at E_{cm} = 13 TeV. See their Figs. 3 and 4 for the limits on cross section times branching ratio for $m_{H_2^0}$ = 0.2–2.0 TeV.

[101] KHACHATRYAN 17R search for production of a narrow scalar resonance decaying to $\gamma\gamma$ in 12.9 fb^{-1} (taken in 2016) of pp collisions at E_{cm} = 13 TeV. See their Fig. 2 for limits on cross section times branching ratio for $m_{H_2^0}$ = 0.5–4.5 TeV for several values of its width-to-mass ratio. Limits from combination with KHACHATRYAN 16M are shown in their Figs. 4 and 6.

[102] SIRUNYAN 17CN search for a narrow scalar resonance decaying to $HH \to b\overline{b}\tau^+\tau^-$ in 18.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 5 (above) and Table II for limits on the cross section times branching ratios for $m_{H_2^0}$ = 0.3–1 TeV, and Fig. 6 (above) and Table III for the corresponding limits by combining with data from KHACHATRYAN 16BQ and KHACHATRYAN 15R.

[103] SIRUNYAN 17Y search for production of a scalar resonance decaying to $Z\gamma$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV and 2.7 fb^{-1} at E_{cm} = 13 TeV. See their Figs. 3, 4 and Table 3 for limits on cross section times branching ratio for $m_{H_2^0}$ = 0.7–3.0 TeV, and Fig. 5 for the corresponding limits for $m_{H_2^0}$ = 0.2–3.0 TeV from combination with KHACHATRYAN 17D data.

[104] AABOUD 16AB search for associated production of WH with the decay $H \to A^0A^0 \to b\overline{b}b\overline{b}$ in 3.2 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 8 for limits on cross section times branching ratios for m_{A^0} = 20–60 GeV.

[105] AABOUD 16AE search for production of a narrow scalar resonance decaying to W^+W^- and ZZ in 3.2 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 4 for limits on cross section times branching ratio for $m_{H_2^0}$ = 0.5–3 TeV.

[106] AABOUD 16H search for production of a scalar resonance decaying to $\gamma\gamma$ in 3.2 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 12 for limits on cross section times branching ratio for $m_{H_2^0}$ = 0.2–2 TeV with different assumptions on the width.

[107] AABOUD 16I search for a narrow scalar resonance decaying to $HH \to b\overline{b}b\overline{b}$ in 3.2 fb^{-1} of pp collisions at E_{cm} = 13 TeV. See their Fig. 10(c) for limits on cross section times branching ratios for $m_{H_2^0}$ = 0.5–3 TeV.

[108] AAD 16AX search for production of a heavy H state decaying to ZZ in the final states $\ell^+\ell^-\ell^+\ell^-$, $\ell^+\ell^-\nu\overline{\nu}$, $\ell^+\ell^-q\overline{q}$, and $\nu\overline{\nu}q\overline{q}$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig.12 for upper limits on $\sigma(H)$ B($H \to ZZ$) for m_H ranging from 140 GeV to 1000 GeV.

[109] AAD 16C search for production of a heavy H state decaying to W^+W^- in the final states $\ell\nu\ell\nu$ and $\ell\nu qq$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Figs. 12, 13, and 16 for upper limits on $\sigma(H)$ B($H \to W^+W^-$) for m_H ranging from 300 GeV to 1000 or 1500 GeV with various assumptions on the total width of H.

[110] AAD 16L search for the decay $H \to A^0A^0 \to \gamma\gamma\gamma\gamma$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 4 (upper right) for limits on cross section times branching ratios (normalized to the SM H cross section) for m_{A^0} = 10–60 GeV.

[111] AAD 16L search for the decay $H_2^0 \to A^0A^0 \to \gamma\gamma\gamma\gamma$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 4 (lower right) for limits on cross section times branching ratios for $m_{H_2^0}$ = 600 GeV and m_{A^0} = 10–245 GeV, and Table 5 for limits for $m_{H_2^0}$= 300 and 900 GeV.

[112] AALTONEN 16C search for electroweak associated production of $H_1^0H^\pm$ followed by the decays $H^\pm \to H_1^0W^*$, $H_1^0 \to \gamma\gamma$ for $m_{H_1^0}$ = 10–105 GeV and $m_{H^\pm}$ = 30–300 GeV. See their Fig. 3 for excluded parameter region in a two-doublet model in which H_1^0 has no direct decay to fermions.

[113] KHACHATRYAN 16BG search for a narrow scalar resonance decaying to $HH \to b\overline{b}b\overline{b}$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 6 for limits on the cross section times branching ratios for $m_{H_2^0}$ = 1.15–3 TeV.

[114] KHACHATRYAN 16BQ search for a resonance decaying to $HH \to \gamma\gamma b\overline{b}$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 9 for limits on the cross section times branching ratios for $m_{H_2^0}$ = 0.26–1.1 TeV.

[115] KHACHATRYAN 16F search for the decay $H \to H_1^0H_1^0 \to \tau^+\tau^-\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 8 for cross section limits for $m_{H_1^0}$ = 4–8 GeV.

[116] KHACHATRYAN 16M search for production of a narrow resonance decaying to $\gamma\gamma$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV and 3.3 fb^{-1} at E_{cm} = 13 TeV. See their Fig. 3 (top) for limits on cross section times branching ratio for $m_{H_2^0}$ = 0.5–4 TeV.

[117] KHACHATRYAN 16P search for gluon fusion production of an H_2^0 decaying to $HH \to b\overline{b}\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 8 (lower right) for cross section limits for $m_{H_2^0}$ = 260–350 GeV.

[118] KHACHATRYAN 16P search for gluon fusion production of an A^0 decaying to $ZH \to \ell^+\ell^-\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 10 for cross section limits for $m_{H_2^0}$ = 220–350 GeV.

[119] AAD 15BK search for production of a heavy H_2^0 decaying to HH in the final state $b\overline{b}b\overline{b}$ in 19.5 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 14(c) for $\sigma(H_2^0)$ B($H_2^0 \to HH$) for $m_{H_2^0}$ = 500–1500 GeV with $\Gamma_{H_2^0}$ = 1 GeV.

[120] AAD 15BZ search for the decay $H \to A^0A^0 \to \mu^+\mu^-\tau^+\tau^-$ (m_H = 125 GeV) in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 6 for limits on cross section times branching ratio for m_{A^0} = 3.7–50 GeV.

[121] AAD 15BZ search for a state H_2^0 via the decay $H_2^0 \to A^0A^0 \to \mu^+\mu^-\tau^+\tau^-$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 6 for limits on cross section times branching ratio for $m_{H_2^0}$ = 100–500 GeV and m_{A^0} = 5 GeV.

[122] AAD 15CE search for production of a heavy H_2^0 decaying to HH in the final states $b\overline{b}\tau^+\tau^-$ and $\gamma\gamma WW^*$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV and combine with data from AAD 15H and AAD 15BK. A limit $\sigma(H_2^0)$ B($H_2^0 \to HH$) < 2.1–0.011 pb (95% CL) is given for $m_{H_2^0}$ = 260–1000 GeV. See their Fig. 6.

[123] AAD 15H search for production of a heavy H_2^0 decaying to HH in the finalstate $\gamma\gamma b\overline{b}$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV.A limit of $\sigma(H_2^0)$ B($H_2^0 \to HH$) < 3.5–0.7 pb is given for $m_{H_2^0}$ = 260–500 GeV at 95% CL. See their Fig. 3.

[124] AAD 15S search for production of A^0 decaying to $ZH \to \ell^+\ell^-b\overline{b}$, $\nu\overline{\nu}b\overline{b}$ and $\ell^+\ell^-\tau^+\tau^-$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 3 for cross section limits for m_{A^0} = 200–1000 GeV.

[125] KHACHATRYAN 15AW search for production of a heavy state H_2^0 of an electroweak singlet extension of the Standard Model via the decays of H_2^0 to W^+W^- and ZZ in up to 5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and up to 19.7 fb^{-1} at E_{cm} = 8 TeV in the range $m_{H_2^0}$ = 145–1000 GeV. See their Figs. 8 and 9 for limits in the parameter space of the model.

[126] KHACHATRYAN 15BB search for production of a resonance H decaying to $\gamma\gamma$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 7 for limits on cross section times branching ratio for m_H = 150–850 GeV.

[127] KHACHATRYAN 15N search for production of A^0 decaying to $ZH \to \ell^+\ell^-b\overline{b}$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 3 for limits on cross section times branching ratios for m_{A^0} = 225–600 GeV.

[128] KHACHATRYAN 15O search for production of a high-mass narrow resonance A^0 decaying to $ZH \to q\overline{q}\tau^+\tau^-$ in 19.7 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 6 for limits on cross section times branching ratios for m_{A^0} = 800–2500 GeV.

[129] KHACHATRYAN 15R search for a narrow scalar resonance decaying to $HH \to b\overline{b}b\overline{b}$ in 17.9 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 5 (top) for limits on cross section times branching ratios for $m_{H_2^0}$ = 0.27–1.1 TeV.

[130] AAD 14AP search for a second H state decaying to $\gamma\gamma$ in addition to the state at about 125 GeV in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Fig. 4 for limits on cross section times branching ratio for m_H = 65–600 GeV.

[131] AAD 14M search for the decay cascade $H_2^0 \to H^\pm W^\mp \to HW^\pm W^\mp$, H decaying to $b\overline{b}$ in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. See their Table III for limits on cross section times branching ratio for $m_{H_2^0}$= 325–1025 GeV and m_{H^+} = 225–925 GeV.

[132] CHATRCHYAN 14G search for a second H state decaying to $WW^{(*)}$ in addition to the observed signal at about 125 GeV using 4.9 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.4 fb^{-1} at E_{cm} = 8 TeV. See their Fig. 21 (right) for cross section limits in the mass range 110–600 GeV.

[133] KHACHATRYAN 14P search for a second H state decaying to $\gamma\gamma$ in addition to the observed signal at about 125 GeV using 5.1 fb^{-1} of pp collisions at E_{cm} = 7 TeV and 19.7 fb^{-1} at E_{cm} = 8 TeV. See their Figs. 27 and 28 for cross section limits in the mass range 110–150 GeV.

[134] AALTONEN 13P search for production of a heavy Higgs boson H'^0 that decays into a charged Higgs boson $H^\pm$ and a lighter Higgs boson H via the decay chain $H'^0 \to H^\pm W^\mp$, $H^\pm \to W^\pm H$, $H \to b\overline{b}$ in the final state $\ell\nu$ plus 4 jets in 8.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. See their Fig. 4 for limits on cross section times branching ratio in the $m_{H^\pm} - m_{H'^0}$ plane for m_H = 126 GeV.

[135] CHATRCHYAN 13BJ search for H production in the decay chain $H \to A^0A^0$, $A^0 \to \mu^+\mu^-$ in 5.3 fb^{-1} of pp collisions at E_{cm} = 7 TeV. See their Fig. 2 for limits on cross section times branching ratio.

[136] AALTONEN 11P search in 2.7 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV for the decay chain $t \to bH^+$, $H^+ \to W^+A^0$, $A^0 \to \tau^+\tau^-$ with m_{A^0} between 4 and 9 GeV. See their Fig. 4 for limits on B($t \to bH^+$) for $90 < m_{H^+} < 160$ GeV.

[137] ABBIENDI 10 search for $e^+e^- \to ZH$ with the decay chain $H \to \tilde{\chi}_1^0\tilde{\chi}_2^0$, $\tilde{\chi}_2^0 \to \tilde{\chi}_1^0$ + (γ or Z^*), when $\tilde{\chi}_1^0$ and $\tilde{\chi}_2^0$ are nearly degenerate. For a mass difference of 2 (4) GeV, a lower limit on m_H of 108.4 (107.0) GeV (95% CL) is obtained for SM ZH cross section and B($H \to \tilde{\chi}_1^0\tilde{\chi}_2^0$) = 1.

[138] SCHAEL 10 search for the process $e^+e^- \to HZ$ followed by the decay chain $H \to A^0A^0 \to \tau^+\tau^-\tau^+\tau^-$ with $Z \to \ell^+\ell^-$, $\nu\overline{\nu}$ at E_{cm} = 183–209 GeV. For a HZZ coupling equal to the SM value, B($H \to A^0A^0$) = B($A^0 \to \tau^+\tau^-$) = 1, and m_{A^0} = 4–10 GeV, m_H up to 107 GeV is excluded at 95% CL.

[139] ABAZOV 09V search for H production followed by the decay chain $H \to A^0A^0 \to \mu^+\mu^-\mu^+\mu^-$ or $\mu^+\mu^-\tau^+\tau^-$ in 4.2 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. See their Fig. 3 for limits on $\sigma(H)$·B($H \to A^0A^0$) for m_{A^0} = 3.6–19 GeV.

[140] ABBIENDI 05A search for $e^+e^- \to H_1^0A^0$ in general Type-II two-doublet models, with decays H_1^0, $A^0 \to q\overline{q}$, gg, $\tau^+\tau^-$, and $H_1^0 \to A^0A^0$.

[141] ABBIENDI 04K search for $e^+e^- \to HZ$ with H decaying to two jets of any flavor including gg. The limit is for SM production cross section with B($H \to jj$) = 1.

[142] ABDALLAH 04 consider the full combined LEP and LEP2 datasets to set limits on the Higgs coupling to W or Z bosons, assuming SM decays of the Higgs. Results in Fig. 26.

[143] ACHARD 04B search for $e^+e^- \to HZ$ with H decaying to $b\overline{b}$, $c\overline{c}$, or gg. The limit is for SM production cross section with B($H \to jj$) = 1.

[144] ACHARD 04F search for H with anomalous coupling to gauge boson pairs in the processes $e^+e^- \to H\gamma$, e^+e^-H, HZ with decays $H \to f\overline{f}$, $\gamma\gamma$, $Z\gamma$, and W^*W at E_{cm} = 189–209 GeV. See paper for limits.

[145] ABBIENDI 03F search for $H \to$ anything in $e^+e^- \to HZ$, using the recoil mass spectrum of $Z \to e^+e^-$ or $\mu^+\mu^-$. In addition, it searched for $Z \to \nu\overline{\nu}$ and $H \to e^+e^-$ or photons. Scenarios with large width or continuum H mass distribution are considered. See their Figs. 11–14 for the results.

[146] ABBIENDI 03G search for $e^+e^- \to H_1^0Z$ followed by $H_1^0 \to A^0A^0$, $A^0 \to c\overline{c}$, gg, or $\tau^+\tau^-$ in the region $m_{H_1^0}$ = 45–86 GeV and m_{A^0} = 2–11 GeV. See their Fig. 7 for the limits.

[147] Search for associated production of a $\gamma\gamma$ resonance with a Z boson, followed by $Z \to q\overline{q}$, $\ell^+\ell^-$, or $\nu\overline{\nu}$, at $E_{cm} \leq$ 209 GeV. The limit is for a H with SM production cross section and B($H \to f\overline{f}$)=0 for all fermions f.

[148] For B($H \to \gamma\gamma$)=1, $m_H > 113.1$ GeV is obtained.

[149] HEISTER 02M search for $e^+e^- \to HZ$, assuming that H decays to $q\overline{q}$, gg, or $\tau^+\tau^-$ only. The limit assumes SM production cross section.

[150] ABBIENDI 01E search for neutral Higgs bosons in general Type-II two-doublet models, at $E_{cm} \leq$ 189 GeV. In addition to usual final states, the decays H_1^0, $A^0 \to q\overline{q}$, gg are searched for. See their Figs. 15,16 for excluded regions.

[151] ACCIARRI 00R search for $e^+e^- \to H\gamma$ with $H \to b\overline{b}$, $Z\gamma$, or $\gamma\gamma$. See their Fig. 3 for limits on $\sigma \cdot$ B. Explicit limits within an effective interaction framework are also given, for which the Standard Model Higgs search results are used in addition.

[152] ACCIARRI 00R search for the two-photon type processes $e^+e^- \to e^+e^-H$ with $H \to b\overline{b}$ or $\gamma\gamma$. See their Fig. 4 for limits on $\Gamma(H \to \gamma\gamma)$·B($H \to \gamma\gamma$or $b\overline{b}$) for m_H=70–170 GeV.

[153] GONZALEZ-GARCIA 98B use DØ limit for $\gamma\gamma$ events with missing E_T in $p\overline{p}$ collisions (ABBOTT 98) to constrain possible ZH or WH production followed by unconventional $H \to \gamma\gamma$ decay which is induced by higher-dimensional operators. See their Figs. 1 and 2 for limits on the anomalous couplings.

[154] KRAWCZYK 97 analyse the muon anomalous magnetic moment in a two-doublet Higgs model (with type II Yukawa couplings) assuming no H_1^0ZZ coupling and obtain $m_{H_1^0} \gtrsim$ 5 GeV or $m_{A^0} \gtrsim$ 5 GeV for tan$\beta > 50$. Other Higgs bosons are assumed to be much heavier.

[155] ALEXANDER 96H give B($Z \to H\gamma$)×B($H \to q\overline{q}$) < 1–4×10^{-5} (95%CL) and B($Z \to H\gamma$)×B($H \to b\overline{b}$) < 0.7–2×10^{-5} (95%CL) in the range $20 < m_H < 80$ GeV.

Electroweak Constraints on the Standard Model Higgs Boson Mass

Here we list constraints on the mass of the Higgs boson derived from fits to precision electroweak observables, assuming the minimal Standard Model with a doublet Higgs field and three generations of fermions.

VALUE (GeV)	DOCUMENT ID		TECN
$\mathbf{90^{+21}_{-18}}$	[1] HALLER	18	RVUE
• • • We do not use the following data for averages, fits, limits, etc. • • •			
91^{+30}_{-23}	[2] BAAK	12	RVUE
94^{+25}_{-22}	[3] BAAK	12A	RVUE
91^{+31}_{-24}	[4] ERLER	10A	RVUE
129^{+74}_{-49}	[5] LEP-SLC	06	RVUE

[1] HALLER 18 make Standard Model fits to Z and neutral current parameters, m_t, m_W, and Γ_W measurements available in 2018. The direct mass measurement at the LHC is not used in the fit.

[2] BAAK 12 make Standard Model fits to Z and neutral current parameters, m_t, m_W, and Γ_W measurements available in 2010 (using also preliminary data). The quoted result is obtained from a fit that does not include the limit from the direct Higgs searches. The result including direct search data from LEP2, the Tevatron and the LHC is 120^{+12}_{-5} GeV.

[3] BAAK 12A make Standard Model fits to Z and neutral current parameters, m_t, m_W, and Γ_W measurements available in 2012 (using also preliminary data). The quoted result is obtained from a fit that does not include the measured mass value of the signal observed at the LHC and also no limits from direct Higgs searches.

[4] ERLER 10A makes Standard Model fits to Z and neutral current parameters, m_t, m_W measurements available in 2009 (using also preliminary data). The quoted result is obtained from a fit that does not include the limits from the direct Higgs searches. With direct search data from LEP2 and Tevatron added to the fit, the 90% CL (99% CL) interval is 115–148 (114–197) GeV.

[5] LEP-SLC 06 make Standard Model fits to Z parameters from LEP/SLC and m_t, m_W, and Γ_W measurements available in 2005 with $\Delta\alpha^{(5)}_{had}(m_Z) = 0.02758 \pm 0.00035$. The 95% CL limit is 285 GeV.

Charged Higgs Bosons ($H^\pm$ and $H^{\pm\pm}$), Searches for

CONTENTS:

$H^\pm$ (charged Higgs) mass limits for $m_{H^+} < m(top)$

Unless otherwise stated, LEP limits assume $B(H^+ \to \tau^+\nu)+B(H^+ \to c\overline{s})=1$, and hold for all values of $B(H^+ \to \tau^+\nu_\tau)$, and assume H^+ weak isospin of $T_3=+1/2$. In the following, $\tan\beta$ is the ratio of the two vacuum expectation values in two-doublet models (2HDM).

The limits are also applicable to point-like technipions. For a discussion of techniparticles, see the Review of Dynamical Electroweak Symmetry Breaking in this Review.

Limits obtained at the LHC are given in the m_h^{mod-} benchmark scenario, see CARENA 13, and hold for all $\tan\beta$ values.

For limits obtained in hadronic collisions before the observation of the top quark, and based on the top mass values inconsistent with the current measurements, see the 1996 (Physical Review **D54** 1 (1996)) Edition of this Review.

Searches in e^+e^- collisions at and above the Z pole have conclusively ruled out the existence of a charged Higgs in the region $m_{H^+} \lesssim 45$ GeV, and are meanwhile superseded by the searches in higher energy e^+e^- collisions at LEP. Results that are by now obsolete are therefore not included in this compilation, and can be found in a previous Edition (The European Physical Journal **C15** 1 (2000)) of this Review.

In the following, and unless otherwise stated, results from the LEP experiments (ALEPH, DELPHI, L3, and OPAL) are assumed to derive from the study of the $e^+e^- \to H^+H^-$ process. Limits from $b \to s\gamma$ decays are usually stronger in generic 2HDM models than in Supersymmetric models.

[1] AAD 15AF search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to \tau^+\nu$ in 19.5 fb^{-1} of pp collisions at $E_{\rm cm} = 8$ TeV. Upper limits on B($t \to bH^+$) B($H^+ \to \tau\nu$) between 2.3×10^{-3} and 1.3×10^{-2} (95% CL) are given for $m_{H^+} = 80$–160 GeV. See their Fig. 8 for the excluded regions in different benchmark scenarios of the MSSM. The region $m_{H^+} < 140$ GeV is excluded for $\tan\beta > 1$ in the considered scenarios.

[2] KHACHATRYAN 15AX search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to \tau^+\nu$ in 19.7 fb^{-1} of pp collisions at $E_{\rm cm} = 8$ TeV. Upper limits on B($t \to bH^+$) B($H^+ \to \tau\nu$) between 1.2×10^{-2} and 1.5×10^{-3} (95% CL) are given for $m_{H^+} = 80$–160 GeV. See their Fig. 11 for the excluded regions in different benchmark scenarios of the MSSM. The region $m_{H^+} < 155$ GeV is excluded for $\tan\beta > 1$ in the considered scenarios.

[3] LEP 13 give a limit that refers to the Type II scenario. The limit for B($H^+ \to \tau\nu$) = 1 is 94 GeV (95% CL), and for B($H^+ \to cs$) = 1 the region below 80.5 as well as the region 83–88 GeV is excluded (95% CL). LEP 13 also search for the decay mode $H^+ \to A^0W^*$ with $A^0 \to b\overline{b}$, which is not negligible in Type I models. The limit in Type I models is 72.5 GeV (95% CL) if $m_{A^0} > 12$ GeV.

[4] ABBIENDI 12 also search for the decay mode $H^+ \to A^0W^*$ with $A^0 \to b\overline{b}$.

[5] AAD 23AH search for vector boson fusion production of $H^\pm$ decaying to $H^\pm \to W^\pm Z \to \ell^\pm\nu\ell^+\ell^-$ in 139 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 9 for limits on cross section times branching ratio in the Georgi-Machacek model for $m_{H^\pm} = 0.2$–1.0 TeV, and also for limits on the triplet vacuum expectation value fraction.

[6] AAD 23BB search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to c\overline{b}$ in 139 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 8 for limits on the product of branching ratios for $m_{H^+} = 60$–160 GeV.

[7] Charge conjugated states are also implied.

[8] AAD 23BW search for $t \to bH^+$ from pair produced top quarks, with the decay chain $H^+ \to W^+A^0$, $A^0 \to \mu^+\mu^-$ using 139 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 5(b)-(d) for limits on the product of branching ratios for $m_{H^+} = 120$, 140, 160 GeV, and $m_{A^0} = 15$–72 GeV.

[9] TUMASYAN 23AV search for production of $H^\pm$ in association with a top quark, decaying to $H_2^0W^\pm$, $H_2^0 \to \tau^+\tau^-$, using 138 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 9 for limits on production cross section times branching ratios for $m_{H^\pm} = 0.3$–0.7 TeV and $m_{H_2^0} = 0.2$ TeV.

[10] TUMASYAN 22B search for production of scalar resonance decaying to $W^\pm\gamma \to qq\gamma$ in 137 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 5 for limits on cross section times branching ratio for the mass range 0.7–6.0 TeV, assuming narrow width or $\Gamma/M = 0.05$.

[11] AAD 21V search for $\overline{t}bH^+$ associated production followed by $H^+ \to t\overline{b}$ in 139 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 6 for upper limits on cross section times branching ratio for $m_{H^+} = 0.2$–2 TeV. See also their Fig. 7 for the excluded region in the parameter space of the hMSSM and the following MSSM benchmark scenarios: M_h^{125}, $M_h^{125}(\widetilde{\chi})$, $M_h^{125}(\widetilde{\tau})$, M_h^{125}(alignment), $M_{h_1}^{125}$(CPV).

[12] SIRUNYAN 21W search for vector boson fusion production of H^+ decaying to $H^+ \to W^+Z \to \ell^+\nu\ell^+\ell^-$ in 137 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 8 for limits on cross section times branching ratio for $m_{H^+} = 0.2$–3.0 TeV, and also for limits on the fraction of the triplet vev contribution to the W mass in the Georgi-Machacek model.

[13] AAD 20W search for dijet resonances in events with isolated leptons using 139 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. As a byproduct, $H^+ \to t\overline{b}$ produced in association with $\overline{t}b$ is searched for. Limits on the product of cross section times branching ratio for $m_{H^+} = 0.6$–2 TeV are given in their Fig. 5(c).

[14] SIRUNYAN 20AO search for $H^+ \to t\overline{b}$ produced in association with $t(b)$ in all jet final states in 35.9 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 6 for limits on the product of cross section times branching ratio for $m_{H^+} = 0.2$–3 TeV. Limits for s-channel production are also given for $m_{H^+} = 0.8$–3 TeV. See also Fig. 7 for the corresponding limits in scenarios in the minimal supersymmetric standard model. Cross section limits from combined results with SIRUNYAN 20AV are given in Fig. 8.

[15] SIRUNYAN 20AV search for $H^+ \to t\overline{b}$ produced in association with $t(b)$ in final states with one or two leptons, in 35.9 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 5 for limits on the product of cross section times branching ratio for $m_{H^+} = 0.2$–3 TeV, and their Fig. 6 for the corresponding limits in scenarios in the minimal supersymmetric standard model.

[16] SIRUNYAN 20BE search for $t \to bH^+$ followed by the decay $H^+ \to c\overline{s}$ in pair produced top quark events using 35.9 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. Limits on the branching ratio in the range 1.68–0.25% (95%CL) are given for $m_{H^+} = 80$–160 GeV, see their Fig. 4.

[17] SIRUNYAN 19AH search for H^+ in the decay of a pair-produced t quark, or in associated tbH^+ or nonresonant $b\overline{b}H^+W^-$ production, followed by $H^+ \to \tau^+\nu$, in 35.9 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. Upper limits on cross section times branching ratio between 6 pb and 5 fb (95% CL) are given for $m_{H^+} = 80$–3000 GeV (including the non-resonant production near the top quark mass), see their Fig. 6 (left). See their Fig. 6 (right) for the excluded regions in the $m_h^{\rm mod-}$ scenario of the MSSM.

[18] SIRUNYAN 19BP search for vector boson fusion production of H^+ decaying to $H^+ \to W^+Z \to \ell^+\nu\ell^+\ell^-$ in 35.9 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 7 for limits on cross section times branching ratio for $m_{H^+} = 0.3$–2.0 TeV, and also for limits on the fraction of the triplet vev contribution to the W mass in the Georgi-Machacek model.

[19] SIRUNYAN 19CC search for $t \to bH^+$ from pair produced top quarks, with the decay chain $H^+ \to W^+A^0$, $A^0 \to \mu^+\mu^-$ in 35.9 fb^{-1} of pp collisions at $E_{\rm cm} = 13$ TeV. See their Fig. 2 for limits on the product of branching ratios for $m_{A^0} = 15$–75 GeV.

[20] SIRUNYAN 19CQ search for vector boson fusion production of H^+ decaying to $H^+ \to W^+Z \to \ell^+\nu q\overline{q}$ or $q\overline{q}\ell^+\ell^-$ in 35.9 fb^{-1} of pp collisions at $E_{\rm cm}$ = 13 TeV. See their Fig. 5 for limits on cross section times branching ratio for m_{H^+} = 0.6–2.0 TeV, and also for limits on the triplet vacuum expectation value fraction in the Georgi-Machacek model.

[21] AABOUD 18BW search for $\overline{t}bH^+$ associated production or the decay $t \to bH^+$, followed by $H^+ \to \tau^+\nu$, in 36.1 fb^{-1} of pp collisions at $E_{\rm cm}$ = 13 TeV. See their Fig. 8(a) for upper limits on cross section times branching ratio for m_{H^+} = 90–2000 GeV, and Fig. 8(b) for limits on B($t \to bH^+$) B($H^+ \to \tau^+\nu$) for m_{H^+} = 90–160 GeV. See also their Fig. 9 for the excluded region in the hMSSM parameter space.

[22] AABOUD 18CD search for $\overline{t}bH^+$ associated production followed by $H^+ \to t\overline{b}$ in 36.1 fb^{-1} of pp collisions at $E_{\rm cm}$ = 13 TeV. See their Fig. 8 for upper limits on cross section times branching ratio for m_{H^+} = 0.2–2 TeV. See also their Fig. 9 for the excluded region in the parameter space of the $m_h^{\rm mod-}$ and hMSSM scenarios of the MSSM. The theory predictions overlaid to the experimental limits to determine the excluded m_{H^+} range are shown without their respective uncertainty band.

[23] AABOUD 18CH search for vector boson fusion production of $H^\pm$ decaying to $H^\pm \to W^\pm Z \to \ell^\pm\nu\ell^+\ell^-$ in 36.1 fb^{-1} of pp collisions at $E_{\rm cm}$ = 13 TeV. See their Fig. 7 for limits on cross section times branching ratio for $m_{H^\pm}$ = 0.2–0.9 TeV, and also for limits on the triplet vacuum expectation value fraction in the Georgi-Machacek model.

[24] HALLER 18 give 95% CL lower limits on m_{H^+} of 590 GeV in type II two Higgs doublet model from combined data (including an unpublished BELLE result) for B($b \to s\gamma$).

[25] SIRUNYAN 18DO search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to c\overline{b}$ in 19.7 fb^{-1} of pp collisions at $E_{\rm cm}$ = 8 TeV. See their Fig. 3 for upper limits on B($t \to bH^+$) for m_{H^+} = 90–150 GeV assuming that B($H^+ \to c\overline{b}$) = 1 and B($t \to bH^+$) + B($t \to bW^+$) = 1.

[26] MISIAK 17 give 95% CL lower limits on m_{H^+} between 570 and 800 GeV in type II two Higgs doublet model from combined data (including an unpublished BELLE result) for B($b \to s(d)\gamma$).

[27] SIRUNYAN 17AE search for vector boson fusion production of $H^\pm$ decaying to $H^\pm \to W^\pm Z \to \ell^\pm\nu\ell^+\ell^-$ in 15.2 fb^{-1} of pp collisions at $E_{\rm cm}$ = 13 TeV. See their Fig. 3 for limits on cross section times branching ratio for $m_{H^\pm}$ = 0.2–2.0 TeV, and also for limits on the triplet vacuum expectation value fraction in the Georgi-Machacek model.

[28] AABOUD 16A search for $t(b)$ $H^\pm$ associated production followed by $H^+ \to \tau^+\nu$ in 3.2 fb^{-1} of pp collisions at $E_{\rm cm}$ = 13 TeV. Upper limits on $\sigma(t(b)\ H^\pm)$ B($H^+ \to \tau\nu$) between 1.9 pb and 15 fb (95% CL) are given for m_{H^+} = 200–2000 GeV, see their Fig. 6. See their Fig. 7 for the excluded regions in the hMSSM scenario.

[29] AAD 16AJ search for $t(b)$ $H^\pm$ associated production followed by $H^\pm \to tb$ in 20.3 fb^{-1} of pp collisions at $E_{\rm cm}$ = 8 TeV. See their Fig. 6 for upper limits on $\sigma(t(b)\ H^\pm)$ B($H^+ \to tb$) for m_{H^+} = 200–600 GeV.

[30] AAD 16AJ search for $H^\pm$ production from quark-antiquark annihilation, followed by $H^\pm \to tb$, in 20.3 fb^{-1} of pp collisions at $E_{\rm cm}$ = 8 TeV. See their Fig. 10 for upper limits on $\sigma(H^\pm)$ B($H^+ \to tb$) for m_{H^+} = 400–3000 GeV.

[31] AAD 15AF search for $tH^\pm$ associated production followed by $H^\pm \to \tau^\pm\nu$ in 19.5 fb^{-1} of pp collisions at $E_{\rm cm}$ = 8 TeV. Upper limits on $\sigma(tH^\pm)$ B($H^+ \to \tau\nu$) between 760 and 4.5 fb (95% CL) are given for m_{H^+} = 180–1000 GeV. See their Fig. 8 for the excluded regions in different benchmark scenarios of the MSSM.

[32] AAD 15M search for vector boson fusion production of $H^\pm$ decaying to $H^\pm \to W^\pm Z \to q\overline{q}\ell^+\ell^-$ in 20.3 fb^{-1} of pp collisions at $E_{\rm cm}$ = 8 TeV. See their Fig. 2 for limits on cross section times branching ratio for $m_{H^\pm}$ = 200–1000 GeV, and Fig. 3 for limits on thetriplet vacuum expectation value fraction in the Georgi-Machacek model.

[33] KHACHATRYAN 15AX search for $tH^\pm$ associated production followed by $H^\pm \to tb$ in 19.7 fb^{-1} of pp collisions at $E_{\rm cm}$ = 8 TeV. Upper limits on $\sigma(tH^\pm)$ B($H^+ \to t\overline{b}$) between 2.0 and 0.13 pb (95% CL) are given for m_{H^+} = 180–600 GeV. See their Fig. 11 for the excluded regions in different benchmark scenarios of the MSSM.

[34] KHACHATRYAN 15AX search for $tH^\pm$ associated production followed by $H^\pm \to \tau^\pm\nu$ in 19.7 fb^{-1} of pp collisions at $E_{\rm cm}$ = 8 TeV. Upper limits on $\sigma(tH^\pm)$ B($H^+ \to \tau\nu$) between 380 and 25 fb (95% CL) are given for m_{H^+} = 180–600 GeV. See their Fig. 11 for the excluded regions in different benchmark scenarios of the MSSM.

[35] KHACHATRYAN 15BF search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to c\overline{s}$ in 19.7 fb^{-1} of pp collisions at $E_{\rm cm}$ = 8 TeV. Upper limits on B($t \to bH^+$) B($H^+ \to c\overline{s}$) between 1.2×10^{-2} and 6.5×10^{-2} (95% CL) are given for m_{H^+} = 90–160 GeV.

[36] AAD 14M search for the decay cascade $H_2^0 \to H^\pm W^\mp \to H^0 W^\pm W^\mp$, H^0 decaying to $b\overline{b}$ in 20.3 fb^{-1} of pp collisions at $E_{\rm cm}$ = 8 TeV. See their Table III for limits on cross section times branching ratio for $m_{H_2^0}$= 325–1025 GeV and m_{H^+}= 225–925 GeV.

[37] AALTONEN 14A measure B($t \to b\tau\nu$) = 0.096 ± 0.028 using 9 fb^{-1} of $p\overline{p}$ collisions at $E_{\rm cm}$ = 1.96 TeV. For m_{H^+}= 80–140 GeV, this measured value is translated to a limit B($t \to bH^+$) < 0.059 at 95% CL assuming B($H^+ \to \tau^+\nu$) = 1.

[38] AAD 13AC search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to c\overline{s}$ (flavor unidentified) in 4.7 fb^{-1} of pp collisions at $E_{\rm cm}$ = 7 TeV. Upper limits on B($t \to bH^+$) between 0.05 and 0.01 (95%CL) are given for m_{H^+}=90–150 GeV and B($H^+ \to c\overline{s}$)=1.

[39] AAD 13V search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to \tau^+\nu$ through violation of lepton universality with 4.6 fb^{-1} of pp collisions at $E_{\rm cm}$ = 7 TeV. Upper limits on B($t \to bH^+$) between 0.032 and 0.044 (95% CL) are given for m_{H^+} = 90–140 GeV and B($H^+ \to \tau^+\nu$) = 1. By combining with AAD 12BH, the limits improve to 0.008 to 0.034 for m_{H^+} = 90–160 GeV. See their Fig. 7 for the excluded region in the $m_h^{\rm max}$ scenario of the MSSM.

[40] AAD 12BH search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to \tau^+\nu$ with 4.6 fb^{-1} of pp collisions at $E_{\rm cm}$ = 7 TeV. Upper limits on B($t \to bH^+$) between 0.01 and 0.05 (95% CL) are given for m_{H^+} = 90–160 GeV and B($H^+ \to \tau^+\nu$) = 1. See their Fig. 8 for the excluded region in the $m_h^{\rm max}$ scenario of the MSSM.

[41] CHATRCHYAN 12AA search for $t\overline{t}$ production followed by $t \to bH^+$, $H^+ \to \tau^+\nu$ with 2 fb^{-1} of pp collisions at $E_{\rm cm}$ = 7 TeV. Upper limits on B($t \to bH^+$) between 0.019 and 0.041 (95% CL) are given for m_{H^+} = 80–160 GeV and B($H^+ \to \tau^+\nu$)=1.

[42] AALTONEN 11P search in 2.7 fb^{-1} of $p\overline{p}$ collisions at $E_{\rm cm}$ = 1.96 TeV for the decay chain $t \to bH^+$, $H^+ \to W^+A^0$, $A^0 \to \tau^+\tau^-$ with m_{A^0} between 4 and 9 GeV. See their Fig. 4 for limits on B($t \to bH^+$) for 90 < m_{H^+} < 160 GeV.

[43] DESCHAMPS 10 make Type II two Higgs doublet model fits to weak leptonic and semileptonic decays, $b \to s\gamma$, B, B_s mixings, and $Z \to b\overline{b}$. The limit holds irrespective of tanβ.

[44] AALTONEN 09AJ search for $t \to bH^+$, $H^+ \to c\overline{s}$ in $t\overline{t}$ events in 2.2 fb^{-1} of $p\overline{p}$ collisions at $E_{\rm cm}$ = 1.96 TeV. Upper limits on B($t \to bH^+$) between 0.08 and 0.32 (95% CL) are given for m_{H^+} = 60–150 GeV and B($H^+ \to c\overline{s}$) = 1.

[45] ABAZOV 09AC search for $t \to bH^+$, $H^+ \to \tau^+\nu$ in $t\overline{t}$ events in 0.9 fb^{-1} of $p\overline{p}$ collisions at $E_{\rm cm}$ = 1.96 TeV. Upper limits on B($t \to bH^+$) between 0.19 and 0.25 (95% CL) are given for m_{H^+} = 80–155 GeV and B($H^+ \to \tau^+\nu$) = 1. See their Fig. 4 for an excluded region in a MSSM scenario.

[46] ABAZOV 09AG measure $t\overline{t}$ cross sections in final states with ℓ + jets (ℓ = e, μ), $\ell\ell$, and $\tau\ell$ in 1 fb^{-1} of $p\overline{p}$ collisions at $E_{\rm cm}$ = 1.96 TeV, which constrains possible $t \to bH^+$ branching fractions. Upper limits (95% CL) on B($t \to bH^+$) between 0.15 and 0.40 (0.48 and 0.57) are given for B($H^+ \to \tau^+\nu$) = 1 (B($H^+ \to c\overline{s}$) = 1) for m_{H^+} = 80–155 GeV.

[47] ABAZOV 09AI search for $t \to bH^+$ in $t\overline{t}$ events in 1 fb^{-1} of $p\overline{p}$ collisions at $E_{\rm cm}$ = 1.96 TeV. Final states with ℓ + jets (ℓ = e, μ), $\ell\ell$, and $\tau\ell$ are examined. Upper limits on B($t \to bH^+$) (95% CL) between 0.15 and 0.19 (0.19 and 0.22) are given for B($H^+ \to \tau^+\nu$) = 1 (B($H^+ \to c\overline{s}$) = 1) for m_{H^+} = 80–155 GeV. For B($H^+ \to \tau^+\nu$) = 1 also a simultaneous extraction of B($t \to bH^+$) and the $t\overline{t}$ cross section is performed, yielding a limit on B($t \to bH^+$) between 0.12 and 0.26 for m_{H^+} = 80–155 GeV. See their Figs. 5–8 for excluded regions in several MSSM scenarios.

[48] ABAZOV 09P search for H^+ production by $q\overline{q}'$ annihilation followed by $H^+ \to t\overline{b}$ decay in 0.9 fb^{-1} of $p\overline{p}$ collisions at $E_{\rm cm}$ = 1.96 TeV. Cross section limits in several two-doublet models are given for m_{H^+} = 180–300 GeV. A region with 20 $\lesssim$ tanβ $\lesssim$ 70 is excluded (95% CL) for 180 GeV $\lesssim$ m_{H^+} $\lesssim$ 184 GeV in type-I models.

[49] ABULENCIA 06E search for associated H^0W production in $p\overline{p}$ collisions at $E_{\rm cm}$ = 1.96 TeV. A fit is made for $t\overline{t}$ production processes in dilepton, lepton + jets, and lepton + τ final states, with the decays $t \to W^+b$ and $t \to H^+b$ followed by $H^+ \to \tau^+\nu$, $c\overline{s}$, $t^*\overline{b}$, or W^+H^0. Within the MSSM the search is sensitive to the region tanβ < 1 or > 30 in the mass range m_{H^+} = 80–160 GeV. See Fig. 2 for the excluded region in a certain MSSM scenario.

[50] ABDALLAH 04I search for $e^+e^- \to H^+H^-$ with $H^\pm$ decaying to $\tau\nu$, cs, or W^*A^0 in Type-I two-Higgs-doublet models.

[51] ABBIENDI 03 give a limit m_{H^+} > 1.28tanβ GeV (95%CL) in Type II two-doublet models.

[52] ABAZOV 02B search for a charged Higgs boson in top decays with $H^+ \to \tau^+\nu$ at $E_{\rm cm}$=1.8 TeV. For m_{H^+}=75 GeV, the region tanβ > 32.0 is excluded at 95%CL. The excluded mass region extends to over 140 GeV for tanβ values above 100.

[53] BORZUMATI 02 point out that the decay modes such as $b\overline{b}W$, A^0W, and supersymmetric ones can have substantial branching fractions in the mass range explored at LEP II and Tevatron.

[54] ABBIENDI 01Q give a limit tanβ/m_{H^+} < 0.53 GeV^{-1} (95%CL) in Type II two-doublet models.

[55] BARATE 01E give a limit tanβ/m_{H^+} < 0.40 GeV^{-1} (90% CL) in Type II two-doublet models. An independent measurement of $B \to \tau\nu_\tau X$ gives tanβ/m_{H^+} < 0.49 GeV^{-1} (90% CL).

[56] GAMBINO 01 use the world average data in the summer of 2001 B($b \to s\gamma$) = (3.23 ± 0.42) × 10^{-4}. The limit applies for Type-II two-doublet models.

[57] AFFOLDER 00I search for a charged Higgs boson in top decays with $H^+ \to \tau^+\nu$ in $p\overline{p}$ collisions at $E_{\rm cm}$=1.8 TeV. The excluded mass region extends to over 120 GeV for tanβ values above 100 and B($\tau\nu$) = 1. If B($t \to bH^+$) $\gtrsim$ 0.6, m_{H^+} up to 160 GeV is excluded. Updates ABE 97L.

[58] ABBOTT 99E search for a charged Higgs boson in top decays in $p\overline{p}$ collisions at $E_{\rm cm}$=1.8 TeV, by comparing the observed $t\overline{t}$ cross section (extracted from the data assuming the dominant decay $t \to bW^+$) with theoretical expectation. The search is sensitive to regions of the domains tanβ $\lesssim$ 1, 50 < m_{H^+}(GeV) $\lesssim$ 120 and tanβ $\gtrsim$ 40, 50 < m_{H^+} (GeV) $\lesssim$ 160. See Fig. 3 for the details of the excluded region.

[59] ACKERSTAFF 99D measure the Michel parameters ρ, ξ, η, and $\xi\delta$ in leptonic τ decays from $Z \to \tau\tau$. Assuming e-μ universality, the limit m_{H^+} > 0.97 tanβ GeV (95%CL) is obtained for two-doublet models in which only one doublet couples to leptons.

[60] ACCIARRI 97F give a limit m_{H^+} > 2.6 tanβ GeV (90% CL) from their limit on the exclusive $B \to \tau\nu_\tau$ branching ratio.

[61] AMMAR 97B measure the Michel parameter ρ from $\tau \to e\nu\nu$ decays and assumes e/μ universality to extract the Michel η parameter from $\tau \to \mu\nu\nu$ decays. The measurement is translated to a lower limit on m_{H^+} in a two-doublet model m_{H^+} > 0.97 tanβ GeV (90% CL).

[62] COARASA 97 reanalyzed the constraint on the ($m_{H^\pm}$,tanβ) plane derived from the inclusive $B \to \tau\nu_\tau X$ branching ratio in GROSSMAN 95B and BUSKULIC 95. They show that the constraint is quite sensitive to supersymmetric one-loop effects.

[63] GUCHAIT 97 studies the constraints on m_{H^+} set by Tevatron data on $\ell\tau$ final states in $t\overline{t} \to (Wb)(Hb)$, $W \to \ell\nu$, $H \to \tau\nu_\tau$. See Fig. 2 for the excluded region.

[64] MANGANO 97 reconsiders the limit in ACCIARRI 97F including the effect of the potentially large $B_c \to \tau\nu_\tau$ background to $B_u \to \tau\nu_\tau$ decays. Stronger limits are obtained.

[65] STAHL 97 fit τ lifetime, leptonic branching ratios, and the Michel parameters and derive limit m_{H^+} > 1.5 tanβ GeV (90% CL) for a two-doublet model. See also STAHL 94.

[66] ALAM 95 measure the inclusive $b \to s\gamma$ branching ratio at $\Upsilon(4S)$ and give B($b \to s\gamma$)< 4.2×10^{-4} (95% CL), which translates to the limit m_{H^+} >[244 + 63/(tanβ)$^{1.3}$]

GeV in the Type II two-doublet model. Light supersymmetric particles can invalidate this bound.

[67] BUSKULIC 95 give a limit $m_{H^+} > 1.9 \tan\beta$ GeV (90% CL) for Type-II models from $b \to \tau\nu_\tau X$ branching ratio, as proposed in GROSSMAN 94.

$H^\pm$ (charged Higgs) mass limits for $m_{H^+} > m(top)$

Limits obtained at the LHC are given in the m_h^{mod-} benchmark scenario, see CARENA 13, and depend on the $\tan\beta$ values.

[1] AABOUD 18BW search for $\bar{t}bH^+$ associated production in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See also their Fig. 9 for the excluded region in the hMSSM parameter space.

$H^{\pm\pm}$ (doubly-charged Higgs boson) mass limits

This section covers searches for a doubly-charged Higgs boson with couplings to lepton pairs. Its weak isospin T_3 is thus restricted to two possibilities depending on lepton chiralities: $T_3(H^{\pm\pm}) = \pm 1$, with the coupling $g_{\ell\ell}$ to $\ell_L^-\ell_L'^-$ and $\ell_R^+\ell_R'^+$ ("left-handed") and $T_3(H^{\pm\pm}) = 0$, with the coupling to $\ell_R^-\ell_R'^-$ and $\ell_L^+\ell_L'^+$ ("right-handed"). These Higgs bosons appear in some left-right symmetric models based on the gauge group $SU(2)_L \times SU(2)_R \times U(1)$, the type-II seesaw model, and the Zee-Babu model. The two cases are listed separately in the following. Unless noted, one of the lepton flavor combinations is assumed to be dominant in the decay.

Limits for $H^{\pm\pm}$ with $T_3 = \pm 1$

[1] AAD 23AI search for $H^{++}H^{--}$ production using 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. Decay branching ratios B($H^{++} \to \ell^+\ell'^+$) for the six flavor combinations are assumed to be equal, adding up to unity. If the $T_3 = 0$ states are degenerate with the $T_3 = \pm 1$ states, the limit becomes 1080 GeV.

[2] AABOUD 19K search for pair production of $H^{++}H^{--}$ followed by the decay $H^{\pm\pm} \to W^\pm W^\pm$ in 36.1 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The search is interpreted in a doublet-triplet extension of the scalar sector with a vev of 0.1 GeV, leading to B($H^{\pm\pm} \to W^\pm W^\pm$) = 1. See their Fig. 5 for limits on the cross section for $m_{H^{++}}$ between 200 and 700 GeV.

[3] See their Figs. 11(b) and 13 for limits with smaller branching ratios.

[4] AAD 15AG search for $H^{++}H^{--}$ production in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. The limit assumes 100% branching ratio to the specified final state. See their Fig. 5 for limits for arbitrary branching ratios.

[5] AAD 15AP search for $H^{++}H^{--}$ production in 20.3 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. The limit assumes 100% branching ratio to the specified final state.

[6] CHATRCHYAN 12AU search for $H^{++}H^{--}$ production with 4.9 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV. The limit assumes 100% branching ratio to the specified final state. See their Table 6 for limits including associated $H^{++}H^-$ production or assuming different scenarios.

[7] ABDALLAH 03 search for $H^{++}H^{--}$ pair production either followed by $H^{++} \to \tau^+\tau^+$, or decaying outside the detector.

[8] ABBIENDI 02C searches for pair production of $H^{++}H^{--}$, with $H^{\pm\pm} \to \ell^\pm\ell^\pm$ ($\ell,\ell' = e,\mu,\tau$). The limit holds for $\ell = \ell' = \tau$, and becomes stronger for other combinations of leptonic final states. To ensure the decay within the detector, the limit only applies for $g(H\ell\ell) \gtrsim 10^{-7}$.

[9] AAD 21U search for pair production of $H^{++}H^{--}$ followed by the decay $H^{\pm\pm} \to W^\pm W^\pm$ in 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. The search is interpreted in a triplet extension of the SM Higgs sector with a triplet vev of 0.1 GeV, leading to B($H^{\pm\pm} \to W^\pm W^\pm$) = 1. See their Fig. 9(a) for limits on the cross section for $m_{H^{++}}$ between 200 and 600 GeV.

[10] AAD 21U search for associated production of $H^{\pm\pm}H^\mp$ followed by the decays $H^{\pm\pm} \to W^\pm W^\pm$, $H^\pm \to W^\pm Z$ in 139 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. $H^{\pm\pm}$ and $H^\pm$ are assumed to be degenerate in mass within 5 GeV. The search is interpreted in a triplet extension of the SM Higgs sector with a triplet vev of 0.1 GeV, leading to B($H^{\pm\pm} \to W^\pm W^\pm$) = 1. See their Fig. 9(b) for limits on the cross section for $m_{H^{++}}$ between 200 and 600 GeV.

[11] SIRUNYAN 21W search for vector boson fusion production of $H^{\pm\pm}$ decaying to $H^{\pm\pm} \to W^\pm W^\pm \to \ell^\pm\nu\ell^\pm\nu$ in 137 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 8 for limits on cross section times branching ratio for $m_{H^{++}} = 0.2$–3.0 TeV.

[12] SIRUNYAN 19CQ search for $H^{\pm\pm}$ production by vector boson fusion followed by the decay $H^{\pm\pm} \to W^\pm W^\pm \to qq\ell\nu$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 5 for limits on cross section times branching ratio for $m_{H^{\pm\pm}}$ between 0.6 and 2 TeV.

[13] SIRUNYAN 18CC search for $H^{\pm\pm}$ production by vector boson fusion followed by the decay $H^{\pm\pm} \to W^\pm W^\pm$ in 35.9 fb^{-1} of pp collisions at $E_{cm} = 13$ TeV. See their Fig. 3 for limits on cross section times branching ratio for $m_{H^{\pm\pm}}$ between 200 and 1000 GeV.

[14] KANEMURA 15 examine the case where H^{++} decays preferentially to $W^{(*)}W^{(*)}$ and estimate that a lower mass limit of ~ 84 GeV can be derived from the same-sign dilepton data of AAD 15AG if H^{++} decays with 100% branching ratio to $W^{(*)}W^{(*)}$.

[15] KHACHATRYAN 15D search for $H^{\pm\pm}$ production by vector boson fusion followed by the decay $H^{\pm\pm} \to W^\pm W^\pm$ in 19.4 fb^{-1} of pp collisions at $E_{cm} = 8$ TeV. See their Fig. 4 for limits on cross section times branching ratio for $m_{H^{++}}$ between 160 and 800 GeV.

[16] KANEMURA 14 examine the case where H^{++} decays preferentially to $W^{(*)}W^{(*)}$ and estimate that a lower mass limit of ~ 60 GeV can be derived from the same-sign dilepton data of AAD 12CY.

[17] AAD 13Y search for $H^{++}H^{--}$ production in a generic search of events with three charged leptons in 4.6 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV. The limit assumes 100% branching ratio to the specified final state.

[18] AAD 12AY search for $H^{++}H^{--}$ production with 1.6 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV. The limit assumes 100% branching ratio to the specified final state.

[19] AAD 12CQ search for $H^{++}H^{--}$ production with 4.7 fb^{-1} of pp collisions at $E_{cm} = 7$ TeV. The limit assumes 100% branching ratio to the specified final state. See their Table 1 for limits assuming smaller branching ratios.

[20] ABAZOV 12A search for $H^{++}H^{--}$ production in 7.0 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV.

[21] AALTONEN 11AF search for $H^{++}H^{--}$ production in 6.1 fb^{-1} of $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV.

[22] AALTONEN 08AA search for $H^{++}H^{--}$ production in $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The limit assumes 100% branching ratio to the specified final state.

[23] ABAZOV 08V search for $H^{++}H^{--}$ production in $p\overline{p}$ collisions at $E_{cm} = 1.96$ TeV. The limit is for B($H \to \mu\mu$) = 1. The limit is updated in ABAZOV 12A.

[24] AKTAS 06A search for single $H^{\pm\pm}$ production in ep collisions at HERA. Assuming that H^{++} only couples to $e^+\mu^+$ with $g_{e\mu} = 0.3$ (electromagnetic strength), a limit $m_{H^{++}} > 141$ GeV (95% CL) is derived. For the case where H^{++} couples to $e\tau$ only the limit is 112 GeV.

[25] ACOSTA 05L search for $H^{++}H^{--}$ pair production in $p\overline{p}$ collisions. The limit is valid for $g_{\ell\ell'} < 10^{-8}$ so that the Higgs decays outside the detector.

[26] ABAZOV 04E search for $H^{++}H^{--}$ pair production in $H^{\pm\pm} \to \mu^\pm\mu^\pm$. The limit is valid for $g_{\mu\mu} \gtrsim 10^{-7}$.

[27] ABBIENDI 03Q searches for single $H^{\pm\pm}$ via direct production in $e^+e^- \to e^\mp e^\mp H^{\pm\pm}$, and via t-channel exchange in $e^+e^- \to e^+e^-$. In the direct case, and assuming B($H^{\pm\pm} \to \ell^\pm\ell^\pm$) = 1, a 95% CL limit on $h_{ee} < 0.071$ is set for $m_{H^{\pm\pm}} < 160$ GeV (see Fig. 6). In the second case, indirect limits on h_{ee} are set for $m_{H^{\pm\pm}} < 2$ TeV (see Fig. 8).

[28] GORDEEV 97 search for muonium-antimuonium conversion and find $G_{M\overline{M}}/G_F < 0.14$ (90% CL), where $G_{M\overline{M}}$ is the lepton-flavor violating effective four-fermion coupling. This limit may be converted to $m_{H^{++}} > 210$ GeV if the Yukawa couplings of H^{++} to ee and $\mu\mu$ are as large as the weak gauge coupling. For similar limits on muonium-antimuonium conversion, see the muon Particle Listings.

[29] ASAKA 95 point out that H^{++} decays dominantly to four fermions in a large region of parameter space where the limit of ACTON 92M from the search of dilepton modes does not apply.

[30] ACTON 92M limit assumes $H^{\pm\pm} \to \ell^\pm\ell^\pm$ or $H^{\pm\pm}$ does not decay in the detector. Thus the region $g_{\ell\ell} \approx 10^{-7}$ is not excluded.

[31] ACTON 92M from $\Delta\Gamma_Z$ <40 MeV.

[32] SWARTZ 90 assume $H^{\pm\pm} \to \ell^\pm\ell^\pm$ (any flavor). The limits are valid for the Higgs-lepton coupling $g(H\ell\ell) \gtrsim 7.4\times10^{-7}/[m_H/\text{GeV}]^{1/2}$. The limits improve somewhat for ee and $\mu\mu$ decay modes.

[1] AAD 23AI search for $H^{++}H^{--}$ production using 139 fb^{-1} of pp collisions at E_{cm} = 13 TeV. Decay branching ratios B($H^{++} \to \ell^+\ell'^+$) for the six flavor combinations are assumed to be equal, adding up to unity.

[2] See their Figs. 12(b) and 14 for limits with smaller branching ratios.

[3] AAD 15AG search for $H^{++}H^{--}$ production in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. The limit assumes 100% branching ratio to the specified final state. See their Fig. 5 for limits for arbitrary branching ratios.

[4] AAD 15AP search for $H^{++}H^{--}$ production in 20.3 fb^{-1} of pp collisions at E_{cm} = 8 TeV. The limit assumes 100% branching ratio to the specified final state.

[5] ABDALLAH 03 search for $H^{++}H^{--}$ pair production either followed by $H^{++} \to \tau^+\tau^+$, or decaying outside the detector.

[6] ACHARD 03F search for $e^+e^- \to H^{++}H^{--}$ with $H^{\pm\pm} \to \ell^\pm\ell'^\pm$. The limit holds for $\ell = \ell' = \tau$, and slightly different limits apply for other flavor combinations. The limit is valid for $g_{\ell\ell'} \gtrsim 10^{-7}$.

[7] ABBIENDI 02C searches for pair production of $H^{++}H^{--}$, with $H^{\pm\pm} \to \ell^\pm\ell^\pm$ ($\ell,\ell' = e,\mu,\tau$). the limit holds for ℓ=ℓ'=τ, and becomes stronger for other combinations of leptonic final states. To ensure the decay within the detector, the limit only applies for $g(H\ell\ell) \gtrsim 10^{-7}$.

[8] AAD 12AY search for $H^{++}H^{--}$ production with 1.6 fb^{-1} of pp collisions at E_{cm} = 7 TeV. The limit assumes 100% branching ratio to the specified final state.

[9] AAD 12CQ search for $H^{++}H^{--}$ production with 4.7 fb^{-1} of pp collisions at E_{cm} = 7 TeV. The limit assumes 100% branching ratio to the specified final state. See their Table 1 for limits assuming smaller branching ratios.

[10] ABAZOV 12A search for $H^{++}H^{--}$ production in 7.0 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV.

[11] AALTONEN 11AF search for $H^{++}H^{--}$ production in 6.1 fb^{-1} of $p\overline{p}$ collisions at E_{cm} = 1.96 TeV.

[12] ABAZOV 08V search for $H^{++}H^{--}$ production in $p\overline{p}$ collisions at E_{cm}= 1.96 TeV. The limit is for B($H^{++} \to \mu\mu$) = 1. The limit is updated in ABAZOV 12A.

[13] AKTAS 06A search for single $H^{\pm\pm}$ production in ep collisions at HERA. Assuming that H^{++} only couples to $e^+\mu^+$ with $g_{e\mu} = 0.3$ (electromagnetic strength), a limit $m_{H^{++}} > 141$ GeV (95% CL) is derived. For the case where H^{++} couples to $e\tau$ only the limit is 112 GeV.

[14] ACOSTA 05L search for $H^{++}H^{--}$ pair production in $p\overline{p}$ collisions. The limit is valid for $g_{\ell\ell'} < 10^{-8}$ so that the Higgs decays outside the detector.

[15] ABAZOV 04E search for $H^{++}H^{--}$ pair production in $H^{\pm\pm} \to \mu^\pm\mu^\pm$. The limit is valid for $g_{\mu\mu} \gtrsim 10^{-7}$.

[16] ABBIENDI 03Q searches for single $H^{\pm\pm}$ via direct production in $e^+e^- \to e^\mp e^\mp H^{\pm\pm}$, and via t-channel exchange in $e^+e^- \to e^+e^-$. In the direct case, and assuming B($H^{\pm\pm} \to \ell^\pm\ell^\pm$) = 1, a 95% CL limit on $h_{ee} < 0.071$ is set for $m_{H^{\pm\pm}} < 160$ GeV (see Fig. 6). In the second case, indirect limits on h_{ee} are set for $m_{H^{\pm\pm}} < 2$ TeV (see Fig. 8).

[17] GORDEEV 97 search for muonium-antimuonium conversion and find $G_{M\overline{M}}/G_F < 0.14$ (90% CL), where $G_{M\overline{M}}$ is the lepton-flavor violating effective four-fermion coupling. This limit may be converted to $m_{H^{++}} > 210$ GeV if the Yukawa couplings of H^{++} to ee and $\mu\mu$ are as large as the weak gauge coupling. For similar limits on muonium-antimuonium conversion, see the muon Particle Listings.

[18] ACTON 92M limit assumes $H^{\pm\pm} \to \ell^\pm\ell^\pm$ or $H^{\pm\pm}$ does not decay in the detector. Thus the region $g_{\ell\ell} \approx 10^{-7}$ is not excluded.

[19] ACTON 92M from $\Delta\Gamma_Z$ <40 MeV.

[20] SWARTZ 90 assume $H^{\pm\pm} \to \ell^\pm\ell^\pm$ (any flavor). The limits are valid for the Higgs-lepton coupling $g(H\ell\ell) \gtrsim 7.4\times10^{-7}/[m_H/\text{GeV}]^{1/2}$. The limits improve somewhat for ee and $\mu\mu$ decay modes.

New Heavy Bosons (W', Z', leptoquarks, etc.), Searches for

We list here various limits on charged and neutral heavy vector bosons (other than W's and Z's), heavy scalar bosons (other than Higgs bosons), vector or scalar leptoquarks, and axigluons. The latest unpublished results are described in "W' Searches" and "Z' Searches" reviews. For recent searches on scalar bosons which could be identified as Higgs bosons, see the listings in the Higgs boson section.

W'-Boson Searches

MASS LIMITS for W' (Heavy Charged Vector Boson Other Than W) in Hadron Collider Experiments

Couplings of W' to quarks and leptons are taken to be identical with those of W. The following limits are obtained from $p\overline{p}$ or $pp \to W'X$ with W' decaying to the mode indicated in the comments. New decay channels (*e.g.*, $W' \to WZ$) are assumed to be suppressed. The most recent preliminary results can be found in the "W'-boson searches" review above.

[1] AAD 23AH search for resonances produced through Drell-Yan and vector-boson-fusion processes in pp collisions at $\sqrt{s}$ = 13 TeV. See their Fig. 7 and Fig. 8 for limits on $\sigma \cdot B$. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$ produced mainly via Drell-Yan.

[2] AAD 23CC search for resonances decaying to tb in pp collisions at $\sqrt{s}$ = 13 TeV. The limit quoted above is for right-handed W' assuming a W' coupling equal to the SM W coupling. The limit becomes $M_{W'} > 4200$ GeV for left-handed W'. See their Figs. 12 and 13 for limits on $\sigma \cdot B$.

[3] AAD 23L perform a generic search for resonances with events containing a Z decaying into e^+e^- or $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 13 TeV. See their Figs. 6, 7, 8 for model independent limits on $\sigma \cdot B$ for Gaussian-shaped resonances. The limit above is for heavy-vector-triplet W' decaying to WZ with $g_V = 3$ as well as with $g_V = 1$.

[4] AAD 23O search for resonances decaying to HW in pp collisions at $\sqrt{s}$ = 13 TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2950$ GeV for $g_V = 1$.

[5] TUMASYAN 23AP search for resonances decaying to WZ in pp collisions at $\sqrt{s}$ = 13 TeV. The limit quoted above is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 4.8$ TeV assuming $M_{W'} = M_{Z'}$ and combining $W' \to WZ$, $W' \to WH$, $Z' \to WW$, $Z' \to ZH$ channels.

[6] TUMASYAN 23AP search for resonances decaying to WH in pp collisions at $\sqrt{s}$ = 13 TeV. The limit quoted above is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 4.8$ TeV assuming $M_{W'} = M_{Z'}$ and combining $W' \to WZ$, $W' \to WH$, $Z' \to WW$, $Z' \to ZH$ channels.

[7] TUMASYAN 23AW search for SSM W' resonance decaying to $\tau\nu$ in pp collisions at $\sqrt{s}$ = 13 TeV. W–W' intereference and bosonic decays of W' are not included. See their Fig. 6 for limits on $\sigma \cdot B$.

[8] TUMASYAN 22AC search for W' with SM-like couplings in pp collisions at $\sqrt{s}$ = 13 TeV. The diboson decays of W' are assumed to be suppressed. See their Fig. 5 for limits on $\sigma \cdot B$.

[9] TUMASYAN 22D search for resonances produced through Drell-Yan and vector-boson-fusion processes in pp collisions at $\sqrt{s}$ = 13 TeV. See their Fig. 8 for limits on $\sigma \cdot B$. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$ produced mainly via Drell-Yan.

[10] TUMASYAN 22J search for resonances produced through Drell-Yan and vector-boson-fusion processes in pp collisions at $\sqrt{s}$ = 13 TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$, produced mainly via Drell-Yan. See their Fig. 9 for limits on $\sigma \cdot B$.

[11] TUMASYAN 22R search for resonances decaying to WZ in pp collisions at $\sqrt{s}$ = 13 TeV. The quoted limit is for heavy-vector-triplet W' produced mainly via Drell-Yan. See their Fig. 8 for limits on $\sigma \cdot B$.

[12] SIRUNYAN 21Y search for resonances decaying to tb in pp collisions at $\sqrt{s}$ = 13 TeV. See their Fig. 2 for limits on $\sigma \cdot$ B($W' \to tb$).

[13] AAD 20AJ search for resonances decaying to HW in pp collisions at $\sqrt{s}$ = 13 TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2900$ GeV for $g_V = 1$. See their Fig. 6 for limits on $\sigma \cdot B$.

[14] AAD 20AT search for resonances decaying to WZ in pp collisions at $\sqrt{s}$ = 13 TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 3900$ GeV for $g_V = 1$. See their Fig. 13 for limits on $\sigma \cdot B$.

[15] AAD 20T search for W' with SM-like couplings in pp collisions at $\sqrt{s}$ = 13 TeV. See their Fig. 4(c) for limits on the product of the cross section, acceptance, and branching fraction.

[16] SIRUNYAN 20AI limit is for W' with SM-like coupling using pp collisions at $\sqrt{s}$ = 13 TeV.

[17] SIRUNYAN 20Q search for resonances decaying to WZ in pp collisions at $\sqrt{s}$ = 13 TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$.

[18] AABOUD 19E search for right-handed W' in pp collisions at $\sqrt{s}$ = 13 TeV. See their Fig. 8 for limit on on $\sigma \cdot B$.

[19] AAD 19C search for W' with SM-like couplings in pp collisions at $\sqrt{s}$ = 13 TeV. Bosonic decays and $W - W'$ interference are neglected. The limits on e and μ separately are 6.0 and 5.1 TeV respectively. See their Fig. 2 for limits on $\sigma \cdot B$.

[20] AAD 19D search for resonances decaying to WZ in pp collisions at $\sqrt{s}$ = 13 TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 3400$ GeV for $g_V = 1$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{W'} > 3800$ GeV and $M_{W'} > 3500$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig. 9 for limits on $\sigma \cdot B$.

[21] SIRUNYAN 19AY limits shown for W' with SM-like coupling using pp collisions at $\sqrt{s}$ = 13 TeV. $W - W'$ interference and bosonic decays of W' are not included. See their Fig. 5 for limits on $\sigma \cdot B$. Limits in the context of a nonuniversal gauge interaction are shown in Fig. 7. Model independent limits on $\sigma B A \epsilon$ can be seen in Fig. 8.

[22] SIRUNYAN 19CP present a statistical combinations of searches for W' decaying to pairs of bosons or leptons in pp collisions at $\sqrt{s}$ = 13 TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. If we assume $M_{W'} = M_{Z'}$, the limit becomes $M_{W'} > 4500$ GeV for $g_V = 3$ and $M_{W'} > 5000$ GeV for $g_V = 1$. See their Figs. 2 and 3 for limits on $\sigma \cdot B$.

[23] SIRUNYAN 19I search for resonances decaying to HW in pp collisions at $\sqrt{s}$ = 13 TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2800$ GeV if we assume $M_{W'} = M_{Z'}$.

[24] AABOUD 18AF give the limit above for right-handed W' using pp collisions at $\sqrt{s}$ = 13 TeV. These limits also exclude W bosons with left-handed couplings with masses below 2.9 TeV, at the 95% confidence level. $W' \to \ell\nu_R$ is assumed to be forbidden. See their Fig.5 for limits on $\sigma \cdot B$ for both cases of left- and right-handed W'.

[25] AABOUD 18AI search for resonances decaying to HW in pp collisions at $\sqrt{s}$ = 13 TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2670$ GeV for $g_V = 1$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{W'} > 2930$ GeV and $M_{W'} > 2800$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig. 5 for limits on $\sigma \cdot B$.

[26] AABOUD 18AK search for resonances decaying to WZ in pp collisions at $\sqrt{s}$ = 13 TeV. The limit quoted above is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2800$ GeV for $g_V = 1$.

[27] AABOUD 18AL search for resonances decaying to WZ in pp collisions at $\sqrt{s}$ = 13 TeV. The limit quoted above is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2900$ GeV for $g_V = 1$.

[28] AABOUD 18BG limit is for W' with SM-like couplings using pp collisions at $\sqrt{s}$ = 13 TeV. Bosonic decays of W' and $W - W'$ interference are neglected. See Fig. 2 for limits on $\sigma \cdot B$.

[29] AABOUD 18CH search for resonances decaying to WZ in pp collisions at $\sqrt{s}$ = 13 TeV. The limit quoted above is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2260$ GeV for $g_V = 1$.

[30] AABOUD 18F search for resonances decaying to WZ in pp collisions at $\sqrt{s}$ = 13 TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 3000$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{W'} > 3500$ GeV and $M_{W'} > 3100$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.5 for limits on $\sigma \cdot B$.

[31] AABOUD 18K limit is for W' with SM-like coupling using pp collisions at $\sqrt{s}$ = 13 TeV. $W - W'$ interference and bosonic decays of W' are not included. See their Fig. 4 for limit on $\sigma \cdot B$.

[32] SIRUNYAN 18 limit is for right-handed W' using pp collisions at $\sqrt{s}$ = 13 TeV. $W' \to \ell\nu_R$ decay is assumed to be forbidden. The limit becomes $M_{W'} > 3.4$ TeV if $M_{\nu_R} \ll M_{W'}$. See their Fig. 5 for exclusion limits on W' models having both left- and right-handed couplings.

[33] SIRUNYAN 18AX search for resonances decaying to WZ in pp collisions at $\sqrt{s}$ = 13 TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. See their Fig.6 for limits on $\sigma \cdot B$.

[34] SIRUNYAN 18AZ limit is derived for W' with SM-like coupling using pp collisions at $\sqrt{s}$ = 13 TeV. No interference with SM W process is considered. The bosonic decays are assumed to be negligible. See their Fig.6 for limits on $\sigma \cdot B$.

[35] SIRUNYAN 18BK search for resonances decaying to WZ in pp collisions at $\sqrt{s}$ = 13 TeV. The limit quoted above is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 3100$ GeV for $g_V = 1$.

[36] SIRUNYAN 18BO limit is for W' with SM-like coupling using pp collisions at $\sqrt{s}$ = 13 TeV.

[37] SIRUNYAN 18DJ search for resonances decaying to WZ in pp collisions at $\sqrt{s}$ = 13 TeV. The limit quoted above is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2270$ GeV for $g_V = 1$.

[38] SIRUNYAN 18ED search for resonances decaying to HW in pp collisions at $\sqrt{s}$ = 13 TeV. The limit above is for heavy-vector-triplet W' with $g_V = 3$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{W'} > 2900$ GeV and $M_{W'} > 2800$ GeV for $g_V = 3$ and $g_V = 1$, respectively.

[39] SIRUNYAN 18P give this limit for a heavy-vector-triplet W' with $g_V = 3$. If they assume $M_{Z'} = M_{W'}$, the limit increases to $M_{W'} > 3800$ GeV.

[40] AABOUD 17AK search for a new resonance decaying to dijets in pp collisions at $\sqrt{s}$ = 13 TeV. The limit above is for a W' boson having axial-vector SM couplings and decaying to quarks with 75% branching fraction.

[41] AABOUD 17AO search for resonances decaying to HW in pp collisions at $\sqrt{s}$ = 13 TeV. The limit quoted above is for a W' in the heavy-vector-triplet model with $g_V = 3$. See their Fig.4 for limits on $\sigma \cdot B$.

[42] AABOUD 17B search for resonances decaying to HW ($H \to b\overline{b}$, $c\overline{c}$; $W \to \ell\nu$) in pp collisions at $\sqrt{s}$ = 13 TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 1750$ GeV for $g_V = 1$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{W'} > 2310$ GeV and $M_{W'} > 1730$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.3 for limits on $\sigma \cdot B$.

[43] KHACHATRYAN 17J search for right-handed W_R in pp collisions at $\sqrt{s}$ = 13 TeV. W_R is assumed to decay into τ and hypothetical heavy neutrino N_τ, with N_τ decaying into τjj. The quoted limit is for $M_{N_\tau} = M_{W_R}/2$. The limit becomes $M_{W_R} > 2350$ GeV (1630 GeV) for $M_{W_R}/M_{N_\tau} = 0.8$ (0.2). See their Fig. 4 for excluded regions in the $M_{W_R} - M_{N_\tau}$ plane.

[44] KHACHATRYAN 17W search for resonances decaying to dijets in pp collisions at $\sqrt{s}$ = 13 TeV.

[45] KHACHATRYAN 17Z limit is for W' with SM-like coupling using pp collisions at $\sqrt{s}$ = 13 TeV. The bosonic decays of W' and the interference with SM W process are neglected.

[46] SIRUNYAN 17A search for resonances decaying to WZ with $WZ \to \ell\nu q\overline{q}$, $q\overline{q}q\overline{q}$ in pp collisions at $\sqrt{s}$ = 13 TeV. The quoted limit is for heavy-vector-triplet W' with g_V

= 3. The limit becomes $M_{W'} > 2000$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{W'} > 2400$ GeV and $M_{W'} > 2300$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.6 for limits on $\sigma \cdot B$.

[47] SIRUNYAN 17AK search for resonances decaying to WZ or HW in pp collisions at $\sqrt{s}$ = 8 and 13 TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. The limit becomes $M_{W'} > 2300$ GeV for $g_V = 1$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{W'} > 2400$ GeV for both $g_V = 3$ and $g_V = 1$. See their Fig.1 and 2 for limits on $\sigma \cdot B$.

[48] SIRUNYAN 17H search for right-handed W' in pp collisions at $\sqrt{s} = 13$ TeV. W' is assumed to decay into τ and a heavy neutrino N, with N decaying to $\tau q \overline{q}$. The limit above assumes $M_N = M_{W'}/2$.

[49] SIRUNYAN 17I limit is for a right-handed W' using pp collisions at $\sqrt{s} = 13$ TeV. The limit becomes $M_{W'} > 2400$ GeV for $M_{\nu_R} \ll M_{W'}$.

[50] SIRUNYAN 17R search for resonances decaying to HW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$. Mass regions $M_{W'} <$ 2370 GeV and 2870 $< M_{W'} <$ 2970 GeV are excluded for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the excluded mass regions are 1000 $< M_{W'} <$ 2500 GeV and 2760 $< M_{W'} <$ 3300 GeV for $g_V = 3$; 1000 $< M_{W'} <$ 2430 GeV and 2810 $< M_{W'} <$ 3130 GeV for $g_V = 1$. See their Fig.5 for limits on $\sigma \cdot B$.

[51] AABOUD 16AE search for resonances decaying to VV ($V = W$ or Z) in pp collisions at $\sqrt{s} = 13$ TeV. Results from $\nu\nu qq$, $\nu\ell qq$, $\ell\ell qq$ and $qqqq$ final states are combined. The quoted limit is for a heavy-vector-triplet W' with $g_V = 3$ and $M_{W'} = M_{Z'}$.

[52] AABOUD 16V limit is for W' with SM-like coupling using pp collisions at $\sqrt{s} = 13$ TeV. The bosonic decays of W' and the interference with SM W process are neglected.

[53] AAD 16R search for $W' \to WZ$ in pp collisions at $\sqrt{s} = 8$ TeV. $\ell\nu\ell'\ell'$, $\ell\ell q\overline{q}$, $\ell\nu q\overline{q}$, and all hadronic channels are combined. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[54] AAD 16S search for a new resonance decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a W' having SM-like couplings to quarks.

[55] KHACHATRYAN 16AO limit is for a SM-like right-handed W' using pp collisions at $\sqrt{s}$ = 8 TeV. The quoted limit combines $t \to qqb$ and $t \to \ell\nu b$ events.

[56] KHACHATRYAN 16AP search for a resonance decaying to HW in pp collisions at $\sqrt{s}$ = 8 TeV. Both H and W are assumed to decay to fat jets. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$.

[57] KHACHATRYAN 16BD search for resonance decaying to HW in pp collisions at $\sqrt{s}$ = 8 TeV. The quoted limit is for heavy-vector-triplet (HVT) W' with $g_V = 3$. The HVT model $m_{W'} = m_{Z'} > 1.8$ TeV is also obtained by combining $W'/Z' \to WH/ZH \to \ell\nu bb$, $qq\tau\tau$, $qqbb$, and $qqqqqq$ channels.

[58] KHACHATRYAN 16K search for resonances decaying to dijets in pp collisions at $\sqrt{s}$ = 13 TeV.

[59] KHACHATRYAN 16L search for resonances decaying to dijets in pp collisions at $\sqrt{s}$ = 8 TeV with the data scouting technique, increasing the sensitivity to the low mass resonances.

[60] KHACHATRYAN 16O limit is for W' having universal couplings. Interferences with the SM amplitudes are assumed to be absent.

[61] AAD 15AU search for W' decaying into the WZ final state with $W \to q\overline{q}'$, $Z \to \ell^+\ell^-$ using pp collisions at $\sqrt{s} = 8$ TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[62] AAD 15AV limit is for a SM like right-handed W' using pp collisions at $\sqrt{s} = 8$ TeV. $W' \to \ell\nu$ decay is assumed to be forbidden.

[63] AAD 15AZ search for W' decaying into the WZ final state with $W \to \ell\nu$, $Z \to q\overline{q}$ using pp collisions at $\sqrt{s} = 8$ TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[64] AAD 15CP search for W' decaying into the WZ final state with $W \to q\overline{q}$, $Z \to q\overline{q}$ using pp collisions at $\sqrt{s} = 8$ TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[65] AAD 15R limit is for a SM like right-handed W' using pp collisions at $\sqrt{s} = 8$ TeV. $W' \to \ell\nu$ decay is assumed to be forbidden.

[66] AAD 15V search for new resonance decaying to dijets in pp collisions at $\sqrt{s} = 8$ TeV.

[67] KHACHATRYAN 15C search for W' decaying via WZ to fully leptonic final states using pp collisions at $\sqrt{s}$=8 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = M_W M_Z/M^2_{W'}$.

[68] KHACHATRYAN 15T limit is for W' with SM-like coupling which interferes the SM W boson constructively using pp collisions at $\sqrt{s} = 8$ TeV. For W' without interference, the limit becomes > 3280 GeV.

[69] KHACHATRYAN 14O search for right-handed W_R in pp collisions at $\sqrt{s} = 8$ TeV. W_R is assumed to decay into ℓ and hypothetical heavy neutrino N, with N decaying into ℓjj. The quoted limit is for $M_{\nu_{eR}} = M_{\nu_{\mu R}} = M_{W_R}/2$. See their Fig. 3 and Fig. 5 for excluded regions in the $M_{W_R} - M_\nu$ plane.

[70] AAD 23BF search for W' decaying to WZ' in pp collisions at $\sqrt{s} = 13$ TeV. The mass difference between W' and Z' is assumed to be 250 GeV. See their Fig. 9(a) for limits on $\sigma \cdot B$ as a function of $M_{W'}$.

[71] AAD 23CG search for right-handed W_R in pp collisions at $\sqrt{s} = 13$ TeV. W_R is assumed to decay into ℓ and hypothetical heavy neutrino N, with N decaying into ℓjj. See their Fig. 9 for limits in m_N–m_{W_R} plane.

[72] AAD 23CK search for a new resonance decaying to HX ($H \to b\overline{b}$, $X \to q\overline{q}'$) in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 12 for limits on $\sigma \cdot B$.

[73] AAD 23U search for a narrow charged vector boson decaying to $W\gamma$. See their Fig. 8(d) for the exclusion limit in $m_{W'} - \sigma \cdot B$ plane.

[74] TUMASYAN 22 search for KK excited W decaying in cascade to three W via a scalar radion R. See their Fig. 4 for limits in $M_{W'} - M_R$ plane.

[75] TUMASYAN 22AL search for resonances decaying to tB or bT with vector-like quarks B (T) subsequently decaying to bH or bZ (tH or tZ). See their Fig. 7 for limits on $\sigma \cdot B$.

[76] TUMASYAN 22B search for a narrow charged vector boson decaying to $W\gamma$. See their Fig. 5 for limits on $\sigma \cdot B$.

[77] TUMASYAN 22I search for KK excited W decaying in cascade to three W via a scalar radion R. See their Fig. 10 for limits in $M_{W'} - M_R$ plane.

[78] TUMASYAN 22P search for right handed W_R in pp collisiions at $\sqrt{s} = 13$ TeV. W_R is assumed to decay into ℓ and hypothetical heavy neutrino N, with N decaying to ℓjj. See their Fig. 7 for excluded regions in $M_{W_R} - M_N$ plane.

[79] AAD 20AD search for a narrow resonance decaying to a pair of large-radius-jets J_1 and J_2 employing a machine-learning procedure. See their Fig. 3 for limits on $\sigma \cdot B$ depending on assumptions about invariant masses for J_1, J_2, and J_1 J_2.

[80] AAD 20W search for W' decaying to WZ' in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 5(b) for limits on $\sigma \cdot B$ as a function of $m_{Z'}$. The $W' \to WZ'$ branching fraction was chosen to be 0.5 and the mass difference between the W' and Z' was set to 250 GeV.

[81] AABOUD 19B search for right-handed W_R in pp collisions at $\sqrt{s} = 13$ TeV. W_R is assumed to decay into ℓ and hypothetical heavy neutrino N, with N decaying to ℓjj. See their Figs. 7 and 8 for excluded regions in $M_{W_R} - M_N$ plane.

[82] AABOUD 19BB search for right handed W_R in pp collisions at $\sqrt{s} = 13$ TeV. W_R is assumed to decay into ℓ and a boosted hypothetical heavy neutrino N, with N decaying to ℓ and a large radius jet $j = q\overline{q}$. See their Fig. 7 for excluded regions in $M_{W_R} - M_N$ plane.

[83] SIRUNYAN 19V search for a new resonance decaying to a top quark and a heavy vector-like bottom partner B decaying to Hb (or a bottom quark and a heavy vector-like top partner T decaying to Ht) in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 8 for limits on $\sigma \cdot B$.

[84] AABOUD 18AA search for a narrow charged vector boson decaying to $W\gamma$. See their Fig. 9 for the exclusion limit in $M_{W'} - \sigma$B plane.

[85] AABOUD 18AD search for resonances decaying to HX ($H \to b\overline{b}$, $X \to q\overline{q}'$) in pp collisions at $\sqrt{s} = 13$ TeV. See their Figs. 3–5 for limits on $\sigma \cdot$B.

[86] AABOUD 18CJ search for heavy-vector-triplet W' in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for model with $g_V = 3$ assuming $M_{W'} = M_{Z'}$. The limit becomes $M_{W'} > 5500$ GeV for model with $g_V = 1$.

[87] SIRUNYAN 18CV search for right-handed W_R in pp collisions at $\sqrt{s} = 13$ TeV. W_R is assumed to decay into ℓ and hypothetical heavy neutrino N, with N decaying to ℓjj. The quoted limit is for $M_N = M_{W_R}/2$. See their Fig. 6 for excluded regions in the $M_{W_R} - M_N$ plane.

[88] KHACHATRYAN 17U search for resonances decaying to HW ($H \to b\overline{b}$; $W \to \ell\nu$) in pp collisions at $\sqrt{s} = 13$ TeV. The limit on the heavy-vector-triplet model is $M_{Z'} = M_{W'} > 2$ TeV for $g_V = 3$, in which constraints from the $Z' \to HZ$ ($H \to b\overline{b}$; $Z \to \ell^+\ell^-$, $\nu\overline{\nu}$) are combined. See their Fig.3 and Fig.4 for limits on $\sigma \cdot B$.

[89] AAD 15BB search for W' decaying into WH with $W \to \ell\nu$, $H \to b\overline{b}$. See their Fig. 4 for the exclusion limits in the heavy vector triplet benchmark model parameter space.

[90] AALTONEN 15C limit is for a SM-like right-handed W' assuming $W' \to \ell\nu$ decays are forbidden, using $p\overline{p}$ collisions at $\sqrt{s}$=1.96 TeV. See their Fig. 3 for limit on $g_{W'}/g_W$.

[91] KHACHATRYAN 15V search new resonance decaying to dijets in pp collisions at $\sqrt{s}$ = 8 TeV.

[92] AAD 14AT search for a narrow charged vector boson decaying to $W\gamma$. See their Fig. 3a for the exclusion limit in $m_{W'} - \sigma B$ plane.

[93] AAD 14S search for W' decaying into the WZ final state with $W \to \ell\nu$, $Z \to \ell\ell$ using pp collisions at $\sqrt{s}$=8 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[94] KHACHATRYAN 14 search for W' decaying into WZ final state with $W \to q\overline{q}$, $Z \to q\overline{q}$ using pp collisions at $\sqrt{s}$=8 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[95] KHACHATRYAN 14A search for W' decaying into the WZ final state with $W \to \ell\nu$, $Z \to q\overline{q}$, or $W \to q\overline{q}$, $Z \to \ell\ell$. pp collisions data at $\sqrt{s}$=8 TeV are used for the search. See their Fig. 13 for the exclusion limit on the number of events in the mass−width plane.

[96] AAD 13AO search for W' decaying into the WZ final state with $W \to \ell\nu$, $Z \to 2j$ using pp collisions at $\sqrt{s}$=7 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[97] CHATRCHYAN 13AJ search for resonances decaying to WZ pair, using the hadronic decay modes of W and Z, in pp collisions at $\sqrt{s}$=7 TeV. See their Fig. 7 for the limit on the cross section.

[98] CHATRCHYAN 13AQ limit is for W' with SM-like coupling which interferes with the SM W boson using pp collisions at $\sqrt{s}$=7 TeV.

[99] CHATRCHYAN 13E limit is for W' with SM-like coupling which intereferes with the SM W boson using pp collisions at $\sqrt{s}$=7 TeV. For W' with right-handed coupling, the bound becomes >1850 GeV (>1910 GeV) if W' decays to both leptons and quarks (only to quarks). If both left- and right-handed couplings are present, the limit becomes >1640 GeV.

[100] CHATRCHYAN 13U search for W' decaying to the WZ final state, with W decaying into jets, in pp collisions at $\sqrt{s}$=7 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[101] The AAD 12AV quoted limit is for a SM-like right-handed W' using pp collisions at $\sqrt{s}$=7 TeV. $W' \to \ell\nu$ decay is assumed to be forbidden.

[102] AAD 12BB use pp collisions data at $\sqrt{s}$=7 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$.

[103] AAD 12CK search for $pp \to tW'$, $W' \to \overline{t}q$ events in pp collisions. See their Fig. 5 for the limit on $\sigma \cdot$B.

[104] AAD 12CR use pp collisions at $\sqrt{s}$=7 TeV.

[105] AAD 12M search for right-handed W_R in pp collisions at $\sqrt{s} = 7$ TeV. W_R is assumed to decay into ℓ and hypothetical heavy neutrino N, with N decaying into ℓjj. See their Fig. 4 for the limit in the m_N–$m_{W'}$ plane.

[106] AALTONEN 12N search for $p\overline{p} \to tW'$, $W' \to \overline{t}d$ events in $p\overline{p}$ collisions. See their Fig. 3 for the limit on $\sigma \cdot$B.

[107] CHATRCHYAN 12AR search for $pp \to t W'$, $W' \to \bar{t} d$ events in pp collisions. See their Fig. 2 for the limit on $\sigma \cdot B$.

[108] CHATRCHYAN 12BG search for right-handed W_R in pp collisions $\sqrt{s} = 7$ TeV. W_R is assumed to decay into ℓ and hypothetical heavy neutrino N, with N decaying into ℓjj. See their Fig. 3 for the limit in the $m_N - m_{W'}$ plane.

[109] ABAZOV 11H use data from $p\overline{p}$ collisions at $\sqrt{s}$=1.96 TeV. The quoted limit is obtained assuming $W'WZ$ coupling strength is the same as the ordinary WWZ coupling strength in the Standard Model.

[110] ABAZOV 11L limit is for W' with SM-like coupling which interferes with the SM W boson, using $p\overline{p}$ collisions at $\sqrt{s}$=1.96 TeV. For W' with right-handed coupling, the bound becomes >885 GeV (>890 GeV) if W' decays to both leptons and quarks (only to quarks). If both left- and right-handed couplings present, the limit becomes >916 GeV.

[111] AALTONEN 10N use $p\overline{p}$ collision data at $\sqrt{s}$=1.96 TeV. The quoted limit assumes $g_{W'WZ}/g_{WWZ} = (M_W/M_{W'})^2$. See their Fig. 4 for limits in mass-coupling plane.

[112] AALTONEN 09AC search for new particle decaying to dijets using $p\overline{p}$ collisions at $\sqrt{s}$=1.96 TeV.

[113] The ACOSTA 03B quoted limit is for $M_{W'} \gg M_{\nu_R}$, using $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV. For $M_{W'} < M_{\nu_R}$, $M_{W'}$ between 225 and 566 GeV is excluded.

[114] The quoted limit is obtained assuming $W'WZ$ coupling strength is the same as the ordinary WWZ coupling strength in the Standard Model, using $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV. See their Fig. 2 for the limits on the production cross sections as a function of the W' width.

[115] AFFOLDER 01I combine a new bound on $W' \to e\nu$ of 754 GeV, using $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV, with the bound of ABE 00 on $W' \to \mu\nu$ to obtain quoted bound.

[116] ABE 97G search for new particle decaying to dijets using $p\overline{p}$ collisions at $\sqrt{s}$=1.8 TeV.

[117] For bounds on W_R with nonzero right-handed mass, see Fig. 5 from ABACHI 96C.

[118] ABACHI 95E assume that the decay $W' \to WZ$ is suppressed and that the neutrino from W' decay is stable and has a mass significantly less $m_{W'}$.

[119] RIZZO 93 analyses CDF limit on possible two-jet resonances. The limit is sensitive to the inclusion of the assumed K factor.

W_R (Right-Handed W Boson) MASS LIMITS

Assuming a light right-handed neutrino, except for BEALL 82, LANGACKER 89B, and COLANGELO 91. $g_R = g_L$ assumed. [Limits in the section MASS LIMITS for W' below are also valid for W_R if $m_{\nu_R} \ll m_{W_R}$.] Some limits assume manifest left-right symmetry, *i.e.*, the equality of left- and right Cabibbo-Kobayashi-Maskawa matrices. For a comprehensive review, see LANGACKER 89B. Limits on the W_L-W_R mixing angle ζ are found in the next section. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

[1] The quoted limit is for manifest left-right symmetric model.

[2] CZAKON 99 perform a simultaneous fit to charged and neutral sectors.

[3] PRIEELS 14 limit is from $\mu^+ \to e^+\nu\overline{\nu}$ decay parameter ξ'', which is determined by the positron polarization measurement.

[4] WAUTERS 10 limit is from a measurement of the asymmetry parameter of polarized ^{60}Co β decays. The listed limit assumes no mixing.

[5] ZHANG 08 limit uses a lattice QCD calculation of the relevant hadronic matrix elements, while BEALL 82 limit used the vacuum saturation approximation.

[6] MELCONIAN 07 measure the neutrino angular asymmetry in β^+-decays of polarized ^{37}K, stored in a magneto-optical trap. Result is consistent with SM prediction and does not constrain the $W_L - W_R$ mixing angle appreciably.

[7] SCHUMANN 07 limit is from measurements of the asymmetry $\langle \vec{p}_\nu \cdot \sigma_n \rangle$ in the β decay of polarized neutrons. Zero mixing is assumed.

[8] CYBURT 05 limit follows by requiring that three light ν_R's decouple when $T_{dec} > 140$ MeV. For different T_{dec}, the bound becomes $M_{W_R} > 3.3$ TeV $(T_{dec} / 140\ \text{MeV})^{3/4}$.

[9] THOMAS 01 limit is from measurement of β^+ polarization in decay of polarized ^{12}N. The listed limit assumes no mixing.

[10] ACKERSTAFF 99D limit is from τ decay parameters. Limit increase to 145 GeV for zero mixing.

[11] BARENBOIM 98 assumes minimal left-right model with Higgs of $SU(2)_R$ in $SU(2)_L$ doublet. For Higgs in $SU(2)_L$ triplet, m_{W_R} >1100 GeV. Bound calculated from effect of corresponding Z_{LR} on electroweak data through Z–Z_{LR} mixing.

[12] The quoted limit is from μ decay parameters. BARENBOIM 97 also evaluate limit from K_L-K_S mass difference.

[13] STAHL 97 limit is from fit to τ-decay parameters.

[14] ALLET 96 measured polarization-asymmetry correlation in ^{12}Nβ^+ decay. The listed limit assumes zero L-R mixing.

[15] KUZNETSOV 95 limit is from measurements of the asymmetry $\langle \vec{p}_\nu \cdot \sigma_n \rangle$ in the β decay of polarized neutrons. Zero mixing assumed. See also KUZNETSOV 94B.

[16] KUZNETSOV 94B limit is from measurements of the asymmetry $\langle \vec{p}_\nu \cdot \sigma_n \rangle$ in the β decay of polarized neutrons. Zero mixing assumed.

[17] BHATTACHARYYA 93 uses Z-Z' mixing limit from LEP '90 data, assuming a specific Higgs sector of $SU(2)_L \times SU(2)_R \times U(1)$ gauge model. The limit is for m_t=200 GeV and slightly improves for smaller m_t.

[18] SEVERIJNS 93 measured polarization-asymmetry correlation in ^{107}In β^+ decay. The listed limit assumes zero L-R mixing. Value quoted here is from SEVERIJNS 94 erratum.

[19] IMAZATO 92 measure positron asymmetry in $K^+ \to \mu^+\nu_\mu$ decay and obtain $\xi P_\mu > 0.990$ (90% CL). If W_R couples to $u\overline{s}$ with full weak strength (V_{us}^R=1), the result corresponds to m_{W_R} >653 GeV. See their Fig. 4 for m_{W_R} limits for general $|V_{us}^R|^2 = 1 - |V_{ud}^R|^2$.

[20] POLAK 92B limit is from fit to muon decay parameters and is essentially determined by JODIDIO 86 data assuming ζ=0. Supersedes POLAK 91.

[21] AQUINO 91 limits obtained from neutron lifetime and asymmetries together with unitarity of the CKM matrix. Manifest left-right symmetry assumed. Stronger of the two limits also includes muon decay results.

[22] COLANGELO 91 limit uses hadronic matrix elements evaluated by QCD sum rule and is less restrictive than BEALL 82 limit which uses vacuum saturation approximation. Manifest left-right symmetry assumed.

[23] POLAK 91 limit is from fit to muon decay parameters and is essentially determined by JODIDIO 86 data assuming ζ=0. Superseded by POLAK 92B.

[24] BARBIERI 89B limit holds for $m_{\nu_R} \leq 10$ MeV.

[25] LANGACKER 89B limit is for any ν_R mass (either Dirac or Majorana) and for a general class of right-handed quark mixing matrices.

[26] BALKE 88 limit is for $m_{\nu_{eR}} = 0$ and $m_{\nu_{\mu R}} \leq 50$ MeV. Limits come from precise measurements of the muon decay asymmetry as a function of the positron energy.

[27] JODIDIO 86 is the same TRIUMF experiment as STOKER 85 (and CARR 83); however, it uses a different technique. The results given here are combined results of the two techniques. The technique here involves precise measurement of the end-point e^+ spectrum in the decay of the highly polarized μ^+.

[28] STOKER 85 is same TRIUMF experiment as CARR 83. Here they measure the decay e^+ spectrum asymmetry above 46 MeV/c using a muon-spin-rotation technique. Assumed a light right-handed neutrino. Quoted limits are from combining with CARR 83.

[29] BERGSMA 83 set limit m_{W_2}/m_{W_1} >1.9 at CL = 90%.

[30] CARR 83 is TRIUMF experiment with a highly polarized μ^+ beam. Looked for deviation from $V-A$ at the high momentum end of the decay e^+ energy spectrum. Limit from previous world-average muon polarization parameter is m_{W_R} >240 GeV. Assumes a light right-handed neutrino.

[31] BEALL 82 limit is obtained assuming that W_R contribution to K_L^0–K_S^0 mass difference is smaller than the standard one, neglecting the top quark contributions. Manifest left-right symmetry assumed.

Limit on W_L-W_R Mixing Angle ζ

Lighter mass eigenstate $W_1 = W_L \cos\zeta - W_R \sin\zeta$. Light ν_R assumed unless noted. Values in brackets are from cosmological and astrophysical considerations.

[1] ACKERSTAFF 99D limit is from τ decay parameters.

[2] CZAKON 99 perform a simultaneous fit to charged and neutral sectors.

[3] The quoted limit is from μ decay parameters. BARENBOIM 97 also evaluate limit from K_L-K_S mass difference.

[4] MISHRA 92 limit is from the absence of extra large-x, large-y $\overline{\nu}_\mu N \to \overline{\nu}_\mu X$ events at Tevatron, assuming left-handed ν and right-handed $\overline{\nu}$ in the neutrino beam. The result gives $\zeta^2(1 - 2m_{W_1}^2/m_{W_2}^2) < 0.0015$. The limit is independent of ν_R mass.

[5] AQUINO 91 limits obtained from neutron lifetime and asymmetries together with unitarity of the CKM matrix. Manifest left-right asymmetry is assumed.
[6] BARBIERI 89B limit holds for $m_{\nu_R} \leq 10$ MeV.
[7] First JODIDIO 86 result assumes $m_{W_R}=\infty$, second is for unconstrained m_{W_R}.

[14] KHACHATRYAN 17W search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV.
[15] AABOUD 16U search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s} = 13$ TeV.
[16] KHACHATRYAN 15AE search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s} = 8$ TeV.
[17] KHACHATRYAN 15V search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 8$ TeV.
[18] AAD 14V search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s} = 8$ TeV.
[19] BOBOVNIKOV 18 use the ATLAS limits on $\sigma(pp \to Z') \cdot B(Z' \to W^+W^-)$ to constrain the Z-Z' mixing parameter ξ. See their Fig. 11 for limits in $M_{Z'} - \xi$ plane.
[20] AABOUD 16AA search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s} = 13$ TeV.
[21] AAD 15AM search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s} = 8$ TeV.
[22] AAD 13S search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s} = 7$ TeV.
[23] CHATRCHYAN 13A use pp collisions at $\sqrt{s}$=7 TeV.
[24] CHATRCHYAN 13AF search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s} = 7$ TeV and 8 TeV.
[25] AAD 12CC search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s} = 7$ TeV.
[26] CHATRCHYAN 12O search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s} = 7$ TeV.
[27] AALTONEN 11I search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV.
[28] ABAZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to e^+e^- in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV.
[29] The quoted limit assumes $g_{WWZ'}/g_{WWZ} = (M_W/M_{Z'})^2$. See their Fig. 4 for limits in mass-coupling plane.
[30] AALTONEN 09AC search for new particle decaying to dijets.
[31] ERLER 09 give 95% CL limit on the Z-Z' mixing $-0.0026 < \theta < 0.0006$.
[32] ABDALLAH 06C use data $\sqrt{s}$ = 130–207 GeV.
[33] ACOSTA 05R search for resonances decaying to tau lepton pairs in $\overline{p}p$ collisions at $\sqrt{s} = 1.96$ TeV.
[34] ABBIENDI 04G give 95% CL limit on Z-Z' mixing $-0.00422 < \theta < 0.00091$. $\sqrt{s}$ = 91 to 207 GeV.
[35] ABAZOV 01B search for resonances in $p\overline{p} \to e^+e^-$ at $\sqrt{s}$=1.8 TeV. They find $\sigma \cdot B(Z' \to ee) < 0.06$ pb for $M_{Z'} > 500$ GeV.
[36] CHEUNG 01B limit is derived from bounds on contact interactions in a global electroweak analysis.
[37] ABREU 00S uses LEP data at $\sqrt{s}$=90 to 189 GeV.
[38] BARATE 00I search for deviations in cross section and asymmetries in $e^+e^- \to$ fermions at $\sqrt{s}$=90 to 183 GeV. Assume θ=0. Bounds in the mass-mixing plane are shown in their Figure 18.
[39] ERLER 99 give 90%CL limit on the Z-Z' mixing $-0.0041 < \theta < 0.0003$. ρ_0=1 is assumed.
[40] ABE 97S find $\sigma(Z') \times B(e^+e^-, \mu^+\mu^-) < 40$ fb for $m_{Z'} > 600$ GeV at $\sqrt{s}$= 1.8 TeV.
[41] VILAIN 94B assume $m_t = 150$ GeV.
[42] ALITTI 93 search for resonances in the two-jet invariant mass. The limit assumes $B(Z' \to q\overline{q})$=0.7. See their Fig. 5 for limits in the $m_{Z'}$–$B(q\overline{q})$ plane.
[43] RIZZO 93 analyses CDF limit on possible two-jet resonances.
[44] ABE 90F use data for R, $R_{\ell\ell}$, and $A_{\ell\ell}$. They fix $m_W = 80.49 \pm 0.43 \pm 0.24$ GeV and $m_Z = 91.13 \pm 0.03$ GeV.

Limits for Z_{LR}

Z_{LR} is the extra neutral boson in left-right symmetric models. $g_L = g_R$ is assumed unless noted. Values in parentheses assume stronger constraint on the Higgs sector, usually motivated by specific left-right symmetric models (see the Note on the W'). Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino. Direct search bounds assume decays to Standard Model fermions only, unless noted.

[1] DEL-AGUILA 10 give 95% CL limit on the Z-Z' mixing $-0.0012 < \theta < 0.0004$.

[2] ABE 97S find $\sigma(Z') \times B(e^+e^-, \mu^+\mu^-) < 40$ fb for $m_{Z'} > 600$ GeV at $\sqrt{s} = 1.8$ TeV.

[3] TUMASYAN 23BE search for pair production of heavy Majorana neutrinos via the decay of a Z' boson in a final state with $\ell^+\ell^-$ and at least two jets. For cases with $m_N = M_{Z'}/4$, their 95% CL limits are $M_{Z'} > 3.59$ TeV (> 4.10 TeV) in the dielectron (dimuon) channel. See their Fig. 5 for limits on $\sigma \cdot B$.

[4] BOBOVNIKOV 18 use the ATLAS limits on $\sigma(pp \to Z') \cdot B(Z' \to W^+W^-)$ to constrain the Z-Z' mixing parameter ξ. See their Fig. 10 for limits in $M_{Z'} - \xi$ plane.

[5] ERLER 09 give 95% CL limit on the Z-Z' mixing $-0.0013 < \theta < 0.0006$.

[6] ABDALLAH 06C give 95% CL limit $|\theta| < 0.0028$. See their Fig. 14 for limit contours in the mass-mixing plane.

[7] ABBIENDI 04G give 95% CL limit on Z-Z' mixing $-0.00098 < \theta < 0.00190$. See their Fig. 20 for the limit contour in the mass-mixing plane. $\sqrt{s} = 91$ to 207 GeV.

[8] CHEUNG 01B limit is derived from bounds on contact interactions in a global electroweak analysis.

[9] ABREU 00S give 95% CL limit on Z-Z' mixing $|\theta| < 0.0018$. See their Fig. 6 for the limit contour in the mass-mixing plane. $\sqrt{s}$=90 to 189 GeV.

[10] BARATE 00I search for deviations in cross section and asymmetries in $e^+e^- \to$ fermions at $\sqrt{s}$=90 to 183 GeV. Assume θ=0. Bounds in the mass-mixing plane are shown in their Figure 18.

[11] CHAY 00 also find $-0.0003 < \theta < 0.0019$. For g_R free, $m_{Z'} > 430$ GeV.

[12] ERLER 00 discuss the possibility that a discrepancy between the observed and predicted values of Q_W(Cs) is due to the exchange of Z'. The data are better described in a certain class of the Z' models including Z_{LR} and Z_χ.

[13] CASALBUONI 99 discuss the discrepancy between the observed and predicted values of Q_W(Cs). It is shown that the data are better described in a class of models including the Z_{LR} model.

[14] CZAKON 99 perform a simultaneous fit to charged and neutral sectors. Assumes manifest left-right symmetric model. Finds $|\theta| < 0.0042$.

[15] ERLER 99 give 90% CL limit on the Z-Z' mixing $-0.0009 < \theta < 0.0017$.

[16] ERLER 99 assumes 2 Higgs doublets, transforming as 10 of SO(10), embedded in E_6.

[17] BARENBOIM 98 also gives 68% CL limits on the Z-Z' mixing $-0.0005 < \theta < 0.0033$. Assumes Higgs sector of minimal left-right model.

[18] CONRAD 98 limit is from measurements at CCFR, assuming no Z-Z' mixing.

[19] VILAIN 94B assume $m_t = 150$ GeV and θ=0. See Fig. 2 for limit contours in the mass-mixing plane.

[20] RIZZO 93 analyses CDF limit on possible two-jet resonances.

[21] GRIFOLS 90 limit holds for $m_{\nu_R} \lesssim 1$ MeV. A specific Higgs sector is assumed. See also GRIFOLS 90D, RIZZO 91.

[22] BARBIERI 89B limit holds for $m_{\nu_R} \leq 10$ MeV. Bounds depend on assumed supernova core temperature.

Limits for Z_χ

Z_χ is the extra neutral boson in SO(10) $\to$ SU(5) $\times$ U(1)$_\chi$. $g_\chi = e/\cos\theta_W$ is assumed unless otherwise stated. We list limits with the assumption $\rho = 1$ but with no further constraints on the Higgs sector. Values in parentheses assume stronger constraint on the Higgs sector motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

[1] AAD 19L search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s} = 13$ TeV.

[2] AABOUD 17AT search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s} = 13$ TeV.

[3] BOBOVNIKOV 18 use the ATLAS limits on $\sigma(pp \to Z') \cdot B(Z' \to W^+W^-)$ to constrain the Z-Z' mixing parameter ξ. See their Fig. 9 for limits in $M_{Z'} - \xi$ plane.

[4] AABOUD 16U search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s} = 13$ TeV.

[5] AAD 14V search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s} = 8$ TeV.

[6] AAD 12CC search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s} = 7$ TeV.

[7] AALTONEN 11I search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV.

[8] ABAZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to e^+e^- in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV.

[9] DEL-AGUILA 10 give 95% CL limit on the Z-Z' mixing $-0.0011 < \theta < 0.0007$.

[10] AALTONEN 09V search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s} =$ 1.96 TeV.

[11] ERLER 09 give 95% CL limit on the Z-Z' mixing $-0.0016 < \theta < 0.0006$.

[12] ABDALLAH 06C give 95% CL limit $|\theta| < 0.0031$. See their Fig. 14 for limit contours in the mass-mixing plane.

[13] ABULENCIA 05A search for resonances decaying to electron or muon pairs in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV.

[14] ABBIENDI 04G give 95% CL limit on Z-Z' mixing $-0.00099 < \theta < 0.00194$. See their Fig. 20 for the limit contour in the mass-mixing plane. $\sqrt{s} = 91$ to 207 GeV.

[15] BARGER 03B limit is from the nucleosynthesis bound on the effective number of light neutrino δN_ν <1. The quark-hadron transition temperature T_c=150 MeV is assumed. The limit with T_c=400 MeV is >4300 GeV.

[16] CHEUNG 01B limit is derived from bounds on contact interactions in a global electroweak analysis.

[17] ABREU 00S give 95% CL limit on Z-Z' mixing $|\theta| < 0.0017$. See their Fig. 6 for the limit contour in the mass-mixing plane. $\sqrt{s}$=90 to 189 GeV.

[18] BARATE 00I search for deviations in cross section and asymmetries in $e^+e^- \to$ fermions at $\sqrt{s}$=90 to 183 GeV. Assume θ=0. Bounds in the mass-mixing plane are shown in their Figure 18.

[19] CHO 00 use various electroweak data to constrain Z' models assuming m_H=100 GeV. See Fig. 3 for limits in the mass-mixing plane.

[20] ERLER 00 discuss the possibility that a discrepancy between the observed and predicted values of Q_W(Cs) is due to the exchange of Z'. The data are better described in a certain class of the Z' models including Z_{LR} and Z_χ.

[21] ROSNER 00 discusses the possibility that a discrepancy between the observed and predicted values of Q_W(Cs) is due to the exchange of Z'. The data are better described in a certain class of the Z' models including Z_χ.

[22] ERLER 99 give 90% CL limit on the Z-Z' mixing $-0.0020 < \theta < 0.0015$.

[23] ERLER 99 assumes 2 Higgs doublets, transforming as 10 of SO(10), embedded in E_6.

[24] CONRAD 98 limit is from measurements at CCFR, assuming no Z-Z' mixing.

[25] ABE 97S find $\sigma(Z') \times B(e^+e^-, \mu^+\mu^-) < 40$ fb for $m_{Z'} > 600$ GeV at $\sqrt{s} = 1.8$ TeV.

[26] Z-Z' mixing is assumed to be zero. $\sqrt{s} = 57.77$ GeV.

[27] VILAIN 94B assume $m_t = 150$ GeV and θ=0. See Fig. 2 for limit contours in the mass-mixing plane.

[28] FARAGGI 91 limit assumes the nucleosynthesis bound on the effective number of neutrinos $\Delta N_\nu < 0.5$ and is valid for $m_{\nu_R} < 1$ MeV.

[29] ABE 90F use data for R, $R_{\ell\ell}$, and $A_{\ell\ell}$. ABE 90F fix $m_W = 80.49 \pm 0.43 \pm 0.24$ GeV and $m_Z = 91.13 \pm 0.03$ GeV.

[30] Assumes the nucleosynthesis bound on the effective number of light neutrinos ($\delta N_\nu < 1$) and that ν_R is light ($\lesssim 1$ MeV).

[31] GRIFOLS 90 limit holds for $m_{\nu_R} \lesssim 1$ MeV. See also GRIFOLS 90D, RIZZO 91.

Limits for Z_ψ

Z_ψ is the extra neutral boson in $E_6 \to$ SO(10) $\times$ U(1)$_\psi$. $g_\psi = e/\cos\theta_W$ is assumed unless otherwise stated. We list limits with the assumption $\rho = 1$ but with no further constraints on the Higgs sector. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

[3] SIRUNYAN 18BB search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.

[4] AABOUD 17AT search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.

[5] KHACHATRYAN 17T search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 8, 13 TeV.

[6] CHATRCHYAN 12O search for resonances decaying to $\tau^+\tau^-$ in pp collisions at $\sqrt{s}$ = 7 TeV.

[7] BOBOVNIKOV 18 use the ATLAS limits on $\sigma(pp \to Z')\cdot B(Z' \to W^+W^-)$ to constrain the Z-Z' mixing parameter ξ. See their Fig. 10 for limits in $M_{Z'} - \xi$ plane.

[8] AABOUD 16U search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.

[9] KHACHATRYAN 15AE search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 8 TeV.

[10] AAD 14V search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 8 TeV.

[11] CHATRCHYAN 13AF search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 7 TeV and 8 TeV.

[12] AAD 12CC search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 7 TeV.

[13] CHATRCHYAN 12M search for resonances decaying to e^+e^- or $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 7 TeV.

[14] AALTONEN 11I search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.

[15] ABAZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to e^+e^- in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.

[16] DEL-AGUILA 10 give 95% CL limit on the Z-Z' mixing $-0.0019 < \theta < 0.0007$.

[17] AALTONEN 09V search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.

[18] ERLER 09 give 95% CL limit on the Z-Z' mixing $-0.0018 < \theta < 0.0009$.

[19] ABDALLAH 06C give 95% CL limit $|\theta| < 0.0027$. See their Fig. 14 for limit contours in the mass-mixing plane.

[20] ABULENCIA 05A search for resonances decaying to electron or muon pairs in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.

[21] ABBIENDI 04G give 95% CL limit on Z-Z' mixing $-0.00129 < \theta < 0.00258$. See their Fig. 20 for the limit contour in the mass-mixing plane. $\sqrt{s}$ = 91 to 207 GeV.

[22] BARGER 03B limit is from the nucleosynthesis bound on the effective number of light neutrino δN_ν <1. The quark-hadron transition temperature T_c=150 MeV is assumed. The limit with T_c=400 MeV is >1100 GeV.

[23] ABREU 00S give 95% CL limit on Z-Z' mixing $|\theta| < 0.0018$. See their Fig. 6 for the limit contour in the mass-mixing plane. $\sqrt{s}$=90 to 189 GeV.

[24] BARATE 00I search for deviations in cross section and asymmetries in $e^+e^- \to$ fermions at $\sqrt{s}$=90 to 183 GeV. Assume θ=0. Bounds in the mass-mixing plane are shown in their Figure 18.

[25] CHO 00 use various electroweak data to constrain Z' models assuming m_H=100 GeV. See Fig. 3 for limits in the mass-mixing plane.

[26] ERLER 99 give 90% CL limit on the Z-Z' mixing $-0.0013 < \theta < 0.0024$.

[27] CONRAD 98 limit is from measurements at CCFR, assuming no Z-Z' mixing.

[28] ABE 97S find $\sigma(Z')\times B(e^+e^-,\mu^+\mu^-)$< 40 fb for $m_{Z'} > 600$ GeV at $\sqrt{s}$= 1.8 TeV.

[29] VILAIN 94B assume m_t = 150 GeV and θ=0. See Fig. 2 for limit contours in the mass-mixing plane.

[30] ABE 90F use data for R, $R_{\ell\ell}$, and $A_{\ell\ell}$. ABE 90F fix $m_W = 80.49 \pm 0.43 \pm 0.24$ GeV and $m_Z = 91.13 \pm 0.03$ GeV.

[31] Assumes the nucleosynthesis bound on the effective number of light neutrinos ($\delta N_\nu < 1$) and that ν_R is light ($\lesssim$ 1 MeV).

[32] GRIFOLS 90D limit holds for $m_{\nu_R} \lesssim$ 1 MeV. See also RIZZO 91.

Limits for Z_η

Z_η is the extra neutral boson in E_6 models, corresponding to $Q_\eta = \sqrt{3/8}\ Q_\chi - \sqrt{5/8}\ Q_\psi$. $g_\eta = e/\cos\theta_W$ is assumed unless otherwise stated. We list limits with the assumption ρ=1 but with no further constraints on the Higgs sector. Values in parentheses assume stronger constraint on the Higgs sector motivated by superstring models. Values in brackets are from cosmological and astrophysical considerations and assume a light right-handed neutrino.

[1] AABOUD 17AT search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.

[2] BOBOVNIKOV 18 use the ATLAS limits on $\sigma(pp \to Z')\cdot B(Z' \to W^+W^-)$ to constrain the Z-Z' mixing parameter ξ. See their Fig. 9 for limits in $M_{Z'} - \xi$ plane.

[3] AABOUD 16U search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s}$ = 13 TeV.

[4] AAD 12CC search for resonances decaying to e^+e^-, $\mu^+\mu^-$ in pp collisions at $\sqrt{s}$ = 7 TeV.

[5] AALTONEN 11I search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.

[6] ABAZOV 11A, AALTONEN 09T, AALTONEN 07H, and ABULENCIA 06L search for resonances decaying to e^+e^- in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.

[7] DEL-AGUILA 10 give 95% CL limit on the Z-Z' mixing $-0.0023 < \theta < 0.0027$.

[8] AALTONEN 09V search for resonances decaying to $\mu^+\mu^-$ in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.

[9] ERLER 09 give 95% CL limit on the Z-Z' mixing $-0.0047 < \theta < 0.0021$.

[10] ABDALLAH 06C give 95% CL limit $|\theta| < 0.0092$. See their Fig. 14 for limit contours in the mass-mixing plane.

[11] ABULENCIA 05A search for resonances decaying to electron or muon pairs in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.

[12] ABBIENDI 04G give 95% CL limit on Z-Z' mixing $-0.00447 < \theta <$0.00331. See their Fig. 20 for the limit contour in the mass-mixing plane. $\sqrt{s}$ = 91 to 207 GeV.

[13] BARGER 03B limit is from the nucleosynthesis bound on the effective number of light neutrino δN_ν <1. The quark-hadron transition temperature T_c=150 MeV is assumed. The limit with T_c=400 MeV is >3300 GeV.

[14] ABREU 00S give 95% CL limit on Z-Z' mixing $|\theta| < 0.0024$. See their Fig. 6 for the limit contour in the mass-mixing plane. $\sqrt{s}$=90 to 189 GeV.

[15] BARATE 00I search for deviations in cross section and asymmetries in $e^+e^- \to$ fermions at $\sqrt{s}$=90 to 183 GeV. Assume θ=0. Bounds in the mass-mixing plane are shown in their Figure 18.

[16] CHO 00 use various electroweak data to constrain Z' models assuming m_H=100 GeV. See Fig. 3 for limits in the mass-mixing plane.

[17] ERLER 99 give 90% CL limit on the Z-Z' mixing $-0.0062 < \theta < 0.0011$.

[18] CONRAD 98 limit is from measurements at CCFR, assuming no Z-Z' mixing.

[19] ABE 97S find $\sigma(Z')\times B(e^+e^-,\mu^+\mu^-)$< 40 fb for $m_{Z'} > 600$ GeV at $\sqrt{s}$= 1.8 TeV.

[20] VILAIN 94B assume m_t = 150 GeV and θ=0. See Fig. 2 for limit contours in the mass-mixing plane.

[21] ABE 90F use data for R, $R_{\ell\ell}$, and $A_{\ell\ell}$. ABE 90F fix $m_W = 80.49 \pm 0.43 \pm 0.24$ GeV and $m_Z = 91.13 \pm 0.03$ GeV.

[22] These authors claim that the nucleosynthesis bound on the effective number of light neutrinos ($\delta N_\nu < 1$) constrains Z' masses if ν_R is light ($\lesssim$ 1 MeV).

[23] GRIFOLS 90 limit holds for $m_{\nu_R} \lesssim$ 1 MeV. See also GRIFOLS 90D, RIZZO 91.

[1] AAD 23O search for resonances decaying to HZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2800$ GeV for $g_V = 1$.

[2] TUMASYAN 23AF search for resonance decaying to $b\overline{b}$ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet Z' with $g_V = 1$. See their Fig. 4 for limits on $\sigma \cdot B$.

[3] TUMASYAN 23AP search for resonances decaying to WW in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 4.8$ TeV assuming $M_{W'} = M_{Z'}$ and combining $W' \to WZ$, $W' \to WH$, $Z' \to WW$, $Z' \to ZH$ channels.

[4] TUMASYAN 23AP search for resonances decaying to ZH in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 4.8$ TeV assuming $M_{W'} = M_{Z'}$ and combining $W' \to WZ$, $W' \to WH$, $Z' \to WW$, $Z' \to ZH$ channels.

[5] TUMASYAN 22D search for resonances produced through Drell-Yan and vector-boson-fusion processes in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 8 for limits on $\sigma \cdot B$. The quoted limit is for heavy-vector-triplet W' with $g_V = 3$ produced mainly via Drell-Yan.

[6] SIRUNYAN 21X search for resonances decaying to HZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 3500$ GeV for $g_V = 1$.

[7] AAD 20AJ search for resonances decaying to HZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2200$ GeV for $g_V = 1$. See their Fig. 6 for limits on $\sigma \cdot B$.

[8] AAD 20AM search for a resonance decaying to $t\overline{t}$ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for a leptophobic top-color Z' with $\Gamma_{Z'}/M_{Z'} = 0.01$. The limit becomes $M_{Z'} > 4700$ GeV for $\Gamma_{Z'}/M_{Z'} = 0.03$.

[9] AAD 20AT search for resonances decaying to WW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 3500$ GeV for $g_V = 1$. See their Fig. 14 for limits on $\sigma \cdot B$.

[10] SIRUNYAN 20Q search for resonances decaying to WW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$.

[11] AABOUD 19AS search for a resonance decaying to $t\overline{t}$ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for a top-color Z' with $\Gamma_{Z'}/M_{Z'} = 0.01$. Limits are also set on Z' masses in simplified Dark Matter models.

[12] AAD 19D search for resonances decaying to WW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2900$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 3800$ GeV and $M_{Z'} > 3500$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig. 9 for limits on $\sigma \cdot B$.

[13] SIRUNYAN 19AA search for a resonance decaying to $t\bar{t}$ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for a leptophobic top-color Z' with $\Gamma_{Z'}/M_{Z'} = 0.01$.

[14] SIRUNYAN 19CP present a statistical combinations of searches for Z' decaying to pairs of bosons or leptons in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. If we assume $M_{Z'} = M_{W'}$, the limit becomes $M_{Z'} > 4500$ GeV for $g_V = 3$ and $M_{Z'} > 5000$ GeV for $g_V = 1$. See their Figs. 2 and 3 for limits on $\sigma \cdot B$.

[15] SIRUNYAN 19I search for resonances decaying to ZW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2800$ GeV if we assume $M_{Z'} = M_{W'}$.

[16] AABOUD 18AB search for resonances decaying to $b\bar{b}$ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a leptophobic Z' with SM-like couplings to quarks. See their Fig. 6 for limits on $\sigma \cdot B$. Additional limits on a Z' axial-vector mediator in a simplified dark-matter model are shown in Fig. 7.

[17] AABOUD 18AI search for resonances decaying to HZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2650$ GeV for $g_V = 1$. If we assume $M_{W'} = M_{Z'}$, the limit increases $M_{Z'} > 2930$ GeV and $M_{Z'} > 2800$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig. 5 for limits on $\sigma \cdot B$.

[18] AABOUD 18AK search for resonances decaying to WW in pp collisions at $\sqrt{s}$ =1 3 TeV. The limit quoted above is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2750$ GeV for $g_V = 1$.

[19] AABOUD 18B search for resonances decaying to WW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 1$. See their Fig.11 for limits on $\sigma \cdot B$.

[20] AABOUD 18BI search for a resonance decaying to $t\bar{t}$ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for a top-color assisted TC Z' with $\Gamma_{Z'}/M_{Z'} = 0.01$. The limits for wider resonances are available. See their Fig. 14 for limits on $\sigma \cdot B$.

[21] AABOUD 18F search for resonances decaying to WW in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2200$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 3500$ GeV and $M_{Z'} > 3100$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.5 for limits on $\sigma \cdot B$.

[22] SIRUNYAN 18ED search for resonances decaying to HZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit above is for heavy-vector-triplet Z' with $g_V = 3$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 2900$ GeV and $M_{Z'} > 2800$ GeV for $g_V = 3$ and $g_V = 1$, respectively.

[23] SIRUNYAN 18P give this limit for a heavy-vector-triplet Z' with $g_V = 3$. If they assume $M_{Z'} = M_{W'}$, the limit increases to $M_{Z'} > 3800$ GeV.

[24] AABOUD 17AK search for a new resonance decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a leptophobic Z' boson having axial-vector coupling strength with quarks $g_q = 0.2$. The limit is 2100 GeV if $g_q = 0.1$.

[25] AABOUD 17AO search for resonances decaying to HZ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a Z' in the heavy-vector-triplet model with $g_V = 3$. See their Fig.4 for limits on $\sigma \cdot B$.

[26] SIRUNYAN 17AK search for resonances decaying to WW or HZ in pp collisions at $\sqrt{s}$ = 8 and 13 TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 2200$ GeV for g_V =1. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 2400$ GeV for both $g_V = 3$ and $g_V = 1$. See their Fig.1 and 2 for limits on $\sigma \cdot B$.

[27] SIRUNYAN 17Q search for a resonance decaying to $t\bar{t}$ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a resonance with relative width $\Gamma_{Z'} / M_{Z'} = 0.01$. Limits for wider resonances are available. See their Fig.6 for limits on $\sigma \cdot B$.

[28] SIRUNYAN 17R search for resonances decaying to HZ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. Mass regions $M_{Z'} < 1150$ GeV and 1250 GeV $< M_{Z'} < 1670$ GeV are excluded for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the excluded mass regions are 1000 $< M_{Z'} <$ 2500 GeV and 2760 $< M_{Z'} <$ 3300 GeV for $g_V = 3$; 1000 $< M_{Z'} <$ 2430 GeV and 2810 $< M_{Z'} <$ 3130 GeV for $g_V = 1$. See their Fig.5 for limits on $\sigma \cdot B$.

[29] AAD 23BF search for a Dark Matter (DM) simplified Z' produced in association with W in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 9(c) for limits on $\sigma \cdot B$ as a function of $M_{Z'}$.

[30] AAD 23W set limits on a dark Higgs model with a spin-1 mediator Z' and a dark Higgs s. Dark Higgs s is assumed to decay into WW. See their Fig. 9 for limits in $M_{Z'} - M_s$ plane.

[31] AAD 23X set limits on $L_\mu - L_\tau$ of Z' using four-muon final states in pp collisions at $\sqrt{s}$ = 13 TeV. See their Fig. 7 for limits in mass-coupling plane.

[32] ADACHI 23B search for Z' produced in association with $\mu^+\mu^-$ and decaying invisibly in e^+e^- collisions at $\sqrt{s} = 10.58$ GeV. See their Fig. 3 and Fig. 4 for limits in mass-coupling plane.

[33] ADACHI 23F search for resonances decaying to $\tau^+\tau^-$ in $\mu^+\mu^-\tau^+\tau^-$ events in e^+e^- collisions at $\sqrt{s} = 10.58$ GeV. See their Fig. 3 for limits on $\sigma \cdot B$.

[34] HAYRAPETYAN 23D search for $\mu^+\mu^-$ resonance produced in association with one or more b-jets in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 8 for limits in the mass-coupling plane of the B_3–L_2 Z' model.

[35] HAYRAPETYAN 23G search for spin-0 and spin-1 resonances decaying to $\mu^+\mu^-$ in pp collisions at $\sqrt{s} = 13$ TeV in the mass ranges of 1.1–2.6 GeV and 4.2–7.9 GeV. See their Fig. 5 for limits on $\sigma \cdot B$.

[36] LI 23I limits on light Z' couplings are dervied from the steller cooling bounds in the mass range of 10^4–10^6 eV. See their Fig. 4 for limits on dark photon, B–L, L_μ–L_τ, and L_e–$L_{\mu(\tau)}$ models.

[37] MANZARI 23 study supernova cooling induced by the emission of light dark fermions χ assumed to couple with leptons via a new massive vector boson Z'. See their Figs. 4 and 5 for limits in mass-coupling plane.

[38] AAD 22 search for $b\bar{b}Z'$ productions in pp collisions at $\sqrt{s} = 13$ TeV. Z' is assumed to decay into $b\bar{b}$. See their Fig.4 for limits on $\sigma \cdot B$.

[39] AAD 22D search for DM mediator Z' produced in association with a Z boson in pp collisions at $\sqrt{s} = 13$ TeV. Z' is assumed to decay invisibly $Z' \to \chi\chi$. See their Fig. 4 for limits in $M_{Z'} - M_\chi$ plane.

[40] ANDREEV 22 search for missing energy in CERN NA64-e experiment. See their Fig. 7 for limits on couplings of $U(1)$ gauge $L_\mu - L_\tau$ Z' models, in the mass range of 1 MeV $< M_{Z'} <$ 600 MeV with the kinetic $Z' - \gamma$ mixing being determined by μ and τ loops.

[41] BONET 22 obtain limits on Z' coupling from ν-nucleus scattering data collected by the CONUS experiment at the nuclear power plant in Brokdorf. See their Fig. 5 for limits in mass-coupling plane.

[42] COLOMA 22 set limits on Z' coupling from ν-nucleus and ν-e scattering data collected by a Ge detector at the Dresden-II power reactor and the COHERENT experiment. See their Fig. 6 for limits in mass-coupling plane in the mass range of 1 keV $< M_{Z'} <$ 5 GeV.

[43] COLOMA 22A use Borexino Phase-II spectral data to constrain Z' couplings. See their Fig. 5 for limits in mass-coupling plane in the mass range of 10 keV $< M_{Z'} <$ 100 MeV.

[44] CZANK 22 search for Z' produced in association with $\mu^+\mu^-$ in e^+e^- collisions at and near Υ resonances. Z' is assumed to decay into $\mu^+\mu^-$. See their Fig. 8 for limits on $Z'\mu\mu$ couplings.

[45] TUMASYAN 22AA search for Z' production in pp collisions at $\sqrt{s} = 13$ TeV. Z' is assumed to decay into two "semivisible" jets (SVJ), i.e., collimated mixtures of visible and invisible particles. See their Fig. 7 and 8 for limits on $\sigma \cdot B$.

[46] AAD 21AQ limits are for a $B - L$ gauge boson model derived from their measurements on four-lepton differential cross sections. See their Fig. 13 for exclusion limits on the $B - L$ breaking Higgs boson mass.

[47] AAD 21AZ search for DM mediator Z' produced in association with a SM Higgs boson in pp collisions at $\sqrt{s} = 13$ TeV. Z' is assumed to decay invisibly $Z' \to \chi\chi$. See their Fig.7 for limits in $M_{Z'} - M_\chi$ plane.

[48] AAD 21BB search for Z' productions in pp collisions at $\sqrt{s} = 13$ TeV. Z' is assumed to decay into a SM Higgs boson H and an invisible particle A. See their Fig.7 for limits in $M_{Z'} - M_A$ plane.

[49] AAD 21D set limits on a dark Higgs model with a spin-1 mediator Z' and a scalar dark Higgs boson s. Dark Higgs s is assumed to decay into WW or ZZ. See their Fig.4 for limits in $M_{Z'} - M_s$ plane.

[50] AAD 21K search for $\gamma + \not{E}_T$ events in pp collision at $\sqrt{s} = 13$ TeV. See their Fig. 5 for limits on Z' particle invisibly decaying to $\chi\chi$.

[51] BURAS 21 performed global fit to leptophilic Z' models using a large number of observables.

[52] CADEDDU 21 obtain limits on Z' coupling $g_{Z'}$ from coherent ν-nucleus scattering data collected by COHERENT experiment. For limits in the $M_{Z'}$–$g_{Z'}$ plane, see their Figures 3 and 4 for the universal Z' model and Figures 5 and 6 for the $B - L$ model.

[53] COLARESI 21 obtain limits on Z' coupling from coherent ν-nucleus scattering data collected by a Ge detector at the Dresden-II power reactor. See their Fig.7 for limits in mass-coupling plane.

[54] KRIBS 21 set decay-agnostic limits on kinetic mixing parameter between $U(1)_Y$ field and new heavy abelian vector boson (dark photon) field using the HERA ep collision data. See their Fig. 3 for limits in mass-mixing plane.

[55] TUMASYAN 21D search for energetic jets + $\not{E}_T$ events in pp collisions at $\sqrt{s} = 13$ TeV. Z' is assumed to decay into a pair of invisible particles $\chi\chi$. See their Fig. 7 for limits on signal strength in $M_{Z'} - M_\chi$ plane, and Fig. 8 for limits on signal strength in quark and dark matter coupling vs mediator mass.

[56] AAD 20AF search for resonances decaying to $H\gamma$ in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 1c for limits on $\sigma \cdot B$ for the mass range 0.7 $< m_{Z'} <$ 4 TeV.

[57] AAD 20T search for Dark Matter mediator Z' decaying invisibly or decaying to $q\bar{q}$ in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 5 for limits in $M_{Z'} - g_q$ plane from the inclusive category. See their Fig. 7(a) for limits on the product of the cross section, acceptance, b-tagging efficiency, and branching fraction from the 2 b-tag category.

[58] AAD 20W search for a Dark Matter (DM) simplified model Z' produced in association with W in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 5 for limits on Z' production cross section.

[59] AAIJ 20AL search for spin-0 and spin-1 resonances decaying to $\mu^+\mu^-$ in pp collisions at $\sqrt{s} = 13$ TeV in the mass regions $M_{Z'} < 60$ GeV, with non-negligible widths considered above 20 GeV. See their Figs. 7, 8, and 9 for limits on $\sigma \cdot B$.

[60] ADACHI 20 search for production of Z' in e^+e^- collisions. The Z' is assume to decay invisibly. See their Fig. 3 and Fig. 5 for limits on Z' coupling and $\sigma(e^+e^- \to e^\pm\mu^\mp Z')$.

[61] SIRUNYAN 20AI search for broad resonances decaying into dijets in pp collisions at $\sqrt{s}$ = 13 TeV. See their Fig. 11 for exclusion limits in mass-coupling plane.

[62] SIRUNYAN 20AQ search for a narrow resonance lighter than 200 GeV decaying to $\mu^+\mu^-$ in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 3 for limits on Z' kinetic mixing coefficient.

[63] SIRUNYAN 20M search for a narrow resonance with a mass between 350 and 700 GeV in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig.3 for exclusion limits in mass-coupling plane.

[64] AABOUD 19AJ search in pp collisions at $\sqrt{s} = 13$ TeV for a new resonance decaying to $q\bar{q}$ and produced in association with a high p_T photon. For a leptophobic axial-vector Z' in the mass region 250 GeV $< M_{Z'} <$ 950 GeV, the Z' coupling with quarks g_q is constrained below 0.18. See their Fig.2 for limits in $M_{Z'} - g_q$ plane.

[65] AABOUD 19D search in pp collisions at $\sqrt{s} = 13$ TeV for a new resonance decaying to $q\bar{q}$ and produced in association with a high-p_T photon or jet. For a leptophobic axial-vector Z' in the mass region 100 GeV $< M_{Z'} <$ 220 GeV, the Z' coupling with quarks g_q is constrained below 0.23. See their Fig. 6 for limits in $M_{Z'} - g_q$ plane.

[66] AABOUD 19V search for Dark Matter simplified Z' decaying invisibly or decaying to fermion pair in pp collisions at $\sqrt{s} = 13$ TeV.

[67] AAD 19L search for resonances decaying to $\ell^+\ell^-$ in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 4 for limits in the heavy vector triplet model couplings.

[68] LONG 19 uses the weak charge data of Cesium and proton to constrain mass of Z' in the 3-3-1 models.

[69] PANDEY 19 obtain limits on Z' induced neutrino non-standard interaction (NSI) parameter ϵ from LHC and IceCube data. See their Fig.2 for limits in $M_{Z'} - \epsilon$ plane, where $\epsilon = g_q\ g_\nu\ v^2\ /\ (2\ M^2_{Z'})$.

[70] SIRUNYAN 19AL search for a new resonance decaying to a top quark and a heavy vector-like top partner in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 8 for limits on Z' production cross section.

[71] SIRUNYAN 19AN search for a Dark Matter (DM) simplified model Z' decaying to H DM DM in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 7 for limits on the signal strength modifiers.

[72] SIRUNYAN 19CB search in pp collisions at $\sqrt{s} = 13$ TeV for a new resonance decaying to $q\overline{q}$. For a leptophobic Z' in the mass region 50–300 GeV, the Z' coupling with quarks g'_q is constrained below 0.2. See their Figs. 4 and 5 for limits on g'_q in the mass range $50 < M_{Z'} < 450$ GeV.

[73] SIRUNYAN 19CD search in pp collisions at $\sqrt{s}$=13 TeV for a leptophobic Z' produced in association of high p_T ISR photon and decaying to $q\overline{q}$. See their Fig. 2 for limits on the Z' coupling strength g'_q to $q\overline{q}$ in the mass range between 10 and 125 GeV.

[74] SIRUNYAN 19D search for a narrow neutral vector resonance decaying to $H\gamma$. See their Fig. 3 for exclusion limit in $M_{Z'} - \sigma\cdot B$ plane. Upper limits on the production of $H\gamma$ resonances are set as a function of the resonance mass in the range of 720–3250 GeV.

[75] AABOUD 18AA search for a narrow neutral vector boson decaying to $H\gamma$. See their Fig. 10 for the exclusion limit in $M_{Z'} - \sigma B$ plane.

[76] AABOUD 18CJ search for heavy-vector-triplet Z' in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for model with $g_V = 3$ assuming $M_{Z'} = M_{W'}$. The limit becomes $M_{Z'} > 5500$ GeV for model with $g_V = 1$.

[77] AABOUD 18N search for a narrow resonance decaying to $q\overline{q}$ in pp collisions at $\sqrt{s} =$ 13 TeV using trigger level analysis to improve the low mass region sensitivity. See their Fig. 5 for limits in the mass-coupling plane in the Z' mass range 450–1800 GeV.

[78] AAIJ 18AQ search for spin-0 and spin-1 resonances decaying to $\mu^+\mu^-$ in pp collisions at $\sqrt{s} = 7$ and 8 TeV in the mass region near 10 GeV. See their Figs. 4 and 5 for limits on $\sigma\cdot B$.

[79] SIRUNYAN 18DR searches for $\mu^+\mu^-$ resonances produced in association with b-jets in the pp collision data with $\sqrt{s} = 8$ TeV and 13 TeV. An excess of events near $m_{\mu\mu} =$ 28 GeV is observed in the 8 TeV data. See their Fig. 3 for the measured fiducial signal cross sections at $\sqrt{s} = 8$ TeV and the 95% CL upper limits at $\sqrt{s} = 13$ TeV.

[80] SIRUNYAN 18G search for a new resonance decaying to dijets in pp collisions at $\sqrt{s} =$ 13 TeV in the mass range 50–300 GeV. See their Fig.7 for limits in the mass-coupling plane.

[81] SIRUNYAN 18I search for a narrow resonance decaying to $b\overline{b}$ in pp collisions at $\sqrt{s} =$ 8 TeV using dedicated b-tagged dijet triggers to improve the sensitivity in the low mass region. See their Fig. 3 for limits on $\sigma\cdot B$ in the Z' mass range 325–1200 GeV.

[82] AABOUD 17B search for resonances decaying to HZ ($H \to b\overline{b}$, $c\overline{c}$; $Z \to \ell^+\ell^-$, $\nu\overline{\nu}$) in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 1490$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 2310$ GeV and $M_{Z'} > 1730$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.3 for limits on $\sigma\cdot B$.

[83] KHACHATRYAN 17AX search for lepto-phobic resonances decaying to four leptons in pp collisions at $\sqrt{s} = 8$ TeV.

[84] KHACHATRYAN 17U search for resonances decaying to HZ ($H \to b\overline{b}$; $Z \to \ell^+\ell^-$, $\nu\overline{\nu}$) in pp collisions at $\sqrt{s} = 13$ TeV. The limit on the heavy-vector-triplet model is $M_{Z'} = M_{W'} > 2$ TeV for $g_V = 3$, in which constraints from the $W' \to HW$ ($H \to b\overline{b}$; $W \to \ell\nu$) are combined. See their Fig.3 and Fig.4 for limits on $\sigma\cdot B$.

[85] SIRUNYAN 17A search for resonances decaying to WW with $WW \to \ell\nu q\overline{q}$, $q\overline{q}q\overline{q}$ in pp collisions at $\sqrt{s} = 13$ TeV. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$. The limit becomes $M_{Z'} > 1600$ GeV for $g_V = 1$. If we assume $M_{Z'} = M_{W'}$, the limit increases $M_{Z'} > 2400$ GeV and $M_{Z'} > 2300$ GeV for $g_V = 3$ and $g_V = 1$, respectively. See their Fig.6 for limits on $\sigma\cdot B$.

[86] SIRUNYAN 17AP search for resonances decaying into a SM-like Higgs scalar H and a light pseudo scalar A. A is assumed to decay invisibly. See their Fig.9 for limits on $\sigma\cdot B$.

[87] SIRUNYAN 17T search for a new resonance decaying to dijets in pp collisions at $\sqrt{s} =$ 13 TeV in the mass range 100–300 GeV. See their Fig.3 for limits in the mass-coupling plane.

[88] SIRUNYAN 17V search for a new resonance decaying to a top quark and a heavy vector-like top partner T in pp collisions at $\sqrt{s} = 13$ TeV. See their table 5 for limits on the Z' production cross section for various values of $M_{Z'}$ and M_T in the range of $M_{Z'} =$ 1500–2500 GeV and $M_T =$ 700–1500 GeV.

[89] AABOUD 16 search for a narrow resonance decaying into $b\overline{b}$ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a leptophobic Z' with SM-like couplings to quarks. See their Fig.6 for limits on $\sigma\cdot B$.

[90] AAD 16L search for $Z' \to a\gamma$, $a \to \gamma\gamma$ in pp collisions at $\sqrt{s} = 8$ TeV. See their Table 6 for limits on $\sigma\cdot B$.

[91] AAD 16S search for a new resonance decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above is for a leptophobic Z' having coupling strength with quark g_q = 0.3 and is taken from their Figure 3.

[92] KHACHATRYAN 16AP search for a resonance decaying to HZ in pp collisions at $\sqrt{s}$ = 8 TeV. Both H and Z are assumed to decay to fat jets. The quoted limit is for heavy-vector-triplet Z' with $g_V = 3$.

[93] KHACHATRYAN 16E search for a leptophobic top-color Z' decaying to $t\overline{t}$ using pp collisions at $\sqrt{s} = 8$ TeV. The quoted limit assumes that $\Gamma_{Z'}/m_{Z'} = 0.012$. Also $m_{Z'} < 2.9$ TeV is excluded for wider topcolor Z' with $\Gamma_{Z'}/m_{Z'} = 0.1$.

[94] AAD 15AO search for narrow resonance decaying to $t\overline{t}$ using pp collisions at $\sqrt{s} = 8$ TeV. See Fig. 11 for limit on σB.

[95] AAD 15AT search for monotop production plus large missing E_T events in pp collisions at $\sqrt{s} = 8$ TeV and give constraints on a Z' model having $Z'u\overline{t}$ coupling. Z' is assumed to decay invisibly. See their Fig. 6 for limits on $\sigma\cdot B$.

[96] AAD 15CD search for decays of Higgs bosons to 4 ℓ states via Z' bosons, $H \to ZZ' \to 4\ell$ or $H \to Z'Z' \to 4\ell$. See Fig. 5 for the limit on the signal strength of the $H \to ZZ' \to 4\ell$ process and Fig. 16 for the limit on $H \to Z'Z' \to 4\ell$.

[97] KHACHATRYAN 15F search for monotop production plus large missing E_T events in pp collisions at $\sqrt{s} = 8$ TeV and give constraints on a Z' model having $Z'u\overline{t}$ coupling. Z' is assumed to decay invisibly. See Fig. 3 for limits on σB.

[98] KHACHATRYAN 15O search for narrow Z' resonance decaying to ZH in pp collisions at $\sqrt{s} = 8$ TeV. See their Fig. 6 for limit on σB.

[99] AAD 14AT search for a narrow neutral vector boson decaying to $Z\gamma$. See their Fig. 3b for the exclusion limit in $m_{Z'} - \sigma B$ plane.

[100] KHACHATRYAN 14A search for new resonance in the WW ($\ell\nu q\overline{q}$) and the ZZ ($\ell\ell q\overline{q}$) channels using pp collisions at $\sqrt{s}$=8 TeV. See their Fig.13 for the exclusion limit on the number of events in the mass-width plane.

[101] MARTINEZ 14 use various electroweak data to constrain the Z' boson in the 3-3-1 models.

[102] AAD 13AQ search for a leptophobic top-color Z' decaying to $t\overline{t}$. The quoted limit assumes that $\Gamma_{Z'}/m_{Z'} = 0.012$.

[103] CHATRCHYAN 13BM search for top-color Z' decaying to $t\overline{t}$ using pp collisions at $\sqrt{s}$=8 TeV. The quoted limit is for $\Gamma_{Z'}/m_{Z'} = 0.012$.

[104] CHATRCHYAN 13AP search for top-color leptophobic Z' decaying to $t\overline{t}$ using pp collisions at $\sqrt{s}$=7 TeV. The quoted limit is for $\Gamma_{Z'}/m_{Z'} = 0.012$.

[105] AAD 12BV search for narrow resonance decaying to $t\overline{t}$ using pp collisions at $\sqrt{s}$=7 TeV. See their Fig. 7 for limit on $\sigma\cdot$B.

[106] AAD 12K search for narrow resonance decaying to $t\overline{t}$ using pp collisions at $\sqrt{s}$=7 TeV. See their Fig. 5 for limit on $\sigma\cdot$B.

[107] AALTONEN 12AR search for chromophilic Z' in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV. See their Fig. 5 for limit on $\sigma\cdot$B.

[108] AALTONEN 12N search for $p\overline{p} \to tZ'$, $Z' \to \overline{t}u$ events in $p\overline{p}$ collisions. See their Fig. 3 for the limit on $\sigma\cdot$B.

[109] ABAZOV 12R search for top-color Z' boson decaying exclusively to $t\overline{t}$. The quoted limit is for $\Gamma_{Z'}/m_{Z'}$= 0.012.

[110] CHATRCHYAN 12AI search for $pp \to tt$ events and give constraints on a Z' model having $Z'\overline{u}t$ coupling. See their Fig. 4 for the limit in mass-coupling plane.

[111] Search for resonance decaying to $t\overline{t}$. See their Fig. 6 for limit on $\sigma\cdot$B.

[112] Search for narrow resonance decaying to $t\overline{t}$. See their Fig. 4 for limit on $\sigma\cdot$B.

[113] Search for narrow resonance decaying to $t\overline{t}$. See their Fig. 3 for limit on $\sigma\cdot$B.

[114] CHATRCHYAN 11O search for same-sign top production in pp collisions induced by a hypothetical FCNC Z' at $\sqrt{s} = 7$ TeV. See their Fig. 3 for limit in mass-coupling plane.

[115] Search for narrow resonance decaying to $t\overline{t}$. See their Fig. 3 for limit on $\sigma\cdot$B.

[116] Search for narrow resonance decaying to $t\overline{t}$. See their Fig. 2 for limit on $\sigma\cdot$B.

[117] BARGER 03B use the nucleosynthesis bound on the effective number of light neutrino δN_ν. See their Figs. 4–5 for limits in general E_6 motivated models.

[118] CHO 00 use various electroweak data to constrain Z' models assuming m_H=100 GeV. See Fig. 2 for limits in general E_6-motivated models.

[119] CHO 98 study constraints on four-Fermi contact interactions obtained from low-energy electroweak experiments, assuming no Z-Z' mixing.

[120] Search for Z' decaying to dijets at $\sqrt{s}$=1.8 TeV. For Z' with electromagnetic strength coupling, no bound is obtained.

Searches for Z' with Lepton-Flavor-Violating decays

The following limits are obtained from $p\overline{p}$ or $pp \to Z'X$ with Z' decaying to the mode indicated in the comments.

[2] AAD 23CB search for a new particle with lepton-flavor violating decay in pp collisions at $\sqrt{s} = 13$ TeV. See their Figs.4, 5, and 6 for limits on $\sigma\cdot B$.

[3] TUMASYAN 23H search for a new particle with lepton-flavor violating decay in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 4 for limits on $\sigma\cdot B$.

[4] AABOUD 18CM search for a new particle with lepton-flavor violating decay in pp collisions at $\sqrt{s} = 13$ TeV. See their Figs. 4, 5, and 6 for limits on $\sigma\cdot B$.

[5] SIRUNYAN 18AT search for a narrow resonance Z' decaying into $e\mu$ in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig.5 for limit on $\sigma\cdot B$ in the range of 600 GeV $< M_{Z'} <$ 5000 GeV.

[6] AABOUD 16P search for new particle with lepton flavor violating decay in pp collisions at $\sqrt{s} = 13$ TeV. See their Figs.2, 3, and 4 for limits on $\sigma\cdot B$.

[7] KHACHATRYAN 16BE search for new particle Z' with lepton flavor violating decay in pp collisions at $\sqrt{s} = 8$ TeV in the range of 200 GeV $< M_{Z'} <$ 2000 GeV. See their Fig.4 for limits on $\sigma\cdot B$ and their Table 5 for bounds on various masses.

[8] AAD 15O search for new particle Z' with lepton flavor violating decay in pp collisions at $\sqrt{s} = 8$ TeV in the range of 500 GeV $< M_{Z'} <$ 3000 GeV. See their Fig. 2 for limits on σB.

[9] AAD 11H search for new particle Z' with lepton flavor violating decay in pp collisions at $\sqrt{s} = 7$ TeV in the range of 700 GeV $< M_{Z'} <$ 1000 GeV. See their Fig. 3 for limits on $\sigma\cdot B$.

[10] AAD 11Z search for new particle Z' with lepton flavor violating decay in pp collisions at $\sqrt{s}$ = 7 TeV in the range 700 GeV < $M_{Z'}$ < 2000 GeV. See their Fig. 3 for limits on $\sigma \cdot B$.

[11] ABULENCIA 06M search for new particle Z' with lepton flavor violating decay in $p\bar{p}$ collisions at $\sqrt{s}$ = 1.96 TeV in the range of 100 GeV < $M_{Z'}$ < 800 GeV. See their Fig. 4 for limits in the mass-coupling plane.

Indirect Constraints on Kaluza-Klein Gauge Bosons

Bounds on a Kaluza-Klein excitation of the Z boson or photon in d=1 extra dimension. These bounds can also be interpreted as a lower bound on $1/R$, the size of the extra dimension. Unless otherwise stated, bounds assume all fermions live on a single brane and all gauge fields occupy the 4+d-dimensional bulk. See also the section on "Extra Dimensions" in the "Searches" Listings in this *Review*.

• • • We do not use the following data for averages, fits, limits, etc. • • •					
> 4.7		[1] MUECK	02	RVUE	Electroweak
> 3.3	95	[2] CORNET	00	RVUE	$e\nu qq'$
>5000		[3] DELGADO	00	RVUE	ϵ_K
> 2.6	95	[4] DELGADO	00	RVUE	Electroweak
> 3.3	95	[5] RIZZO	00	RVUE	Electroweak
> 2.9	95	[6] MARCIANO	99	RVUE	Electroweak
> 2.5	95	[7] MASIP	99	RVUE	Electroweak
> 1.6	90	[8] NATH	99	RVUE	Electroweak
> 3.4	95	[9] STRUMIA	99	RVUE	Electroweak

[1] MUECK 02 limit is 2σ and is from global electroweak fit ignoring correlations among observables. Higgs is assumed to be confined on the brane and its mass is fixed. For scenarios of bulk Higgs, of brane-SU(2)$_L$, bulk-U(1)$_Y$, and of bulk-SU(2)$_L$, brane-U(1)$_Y$, the corresponding limits are > 4.6 TeV, > 4.3 TeV and > 3.0 TeV, respectively.

[2] Bound is derived from limits on $e\nu qq'$ contact interaction, using data from HERA and the Tevatron.

[3] Bound holds only if first two generations of quarks lives on separate branes. If quark mixing is not complex, then bound lowers to 400 TeV from Δm_K.

[4] See Figs. 1 and 2 of DELGADO 00 for several model variations. Special boundary conditions can be found which permit KK states down to 950 GeV and that agree with the measurement of Q_W(Cs). Quoted bound assumes all Higgs bosons confined to brane; placing one Higgs doublet in the bulk lowers bound to 2.3 TeV.

[5] Bound is derived from global electroweak analysis assuming the Higgs field is trapped on the matter brane. If the Higgs propagates in the bulk, the bound increases to 3.8 TeV.

[6] Bound is derived from global electroweak analysis but considering only presence of the KK W bosons.

[7] Global electroweak analysis used to obtain bound independent of position of Higgs on brane or in bulk.

[8] Bounds from effect of KK states on G_F, α, M_W, and M_Z. Hard cutoff at string scale determined using gauge coupling unification. Limits for d=2,3,4 rise to 3.5, 5.7, and 7.8 TeV.

[9] Bound obtained for Higgs confined to the matter brane with m_H=500 GeV. For Higgs in the bulk, the bound increases to 3.5 TeV.

[1] AAD 23BJ search for scalar leptoquarks decaying to $c\tau$ in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 8 for exclusion limit on σ as function of M_{LQ}.

[2] AAD 23CF search for scalar and vector leptoquarks decaying to $b\tau$. The limit quoted above is for scalar leptoquark. See their Fig. 9 for limits on leptoquark pair production cross sections.

[3] AAD 23CF search for scalar and vector leptoquarks decaying to $b\tau$. The limit quoted above is for vector leptoquark with $\kappa = 1$. The limit becomes $M_{LQ} > 1650$ for vector leptoquark with $\kappa = 0$. See their Fig. 9 for limits on leptoquark pair production cross sections.

[4] AAD 23F search for scalar leptoquarks decaying to $t\nu$ and $b\mu$ in pp collisions at $\sqrt{s} =$ 13 TeV. See their Fig. 9 for exclusion contour in B($b\mu$)−M_{LQ} plane.

[5] AAD 23F search for scalar leptoquarks decaying to $t\nu$ and be in pp collisions at $\sqrt{s} =$ 13 TeV. See their Fig. 9 for exclusion contour in B(be)−M_{LQ} plane.

[6] AAD 23F search for scalar leptoquarks decaying to $t\mu$ and $b\nu$ in pp collisions at $\sqrt{s} =$ 13 TeV. See their Fig. 9 for exclusion contour in B($t\mu$)−M_{LQ} plane.

[7] AAD 23F search for scalar leptoquarks decaying to te and $b\nu$ in pp collisions at $\sqrt{s} =$ 13 TeV. See their Fig. 9 for exclusion contour in B(te)−M_{LQ} plane.

[8] AAD 23F search for $\kappa = 1$ (YM coupling) vector leptoquarks decaying to $t\nu$ and $b\mu$ in pp collisions at $\sqrt{s} = 13$ TeV. If $\kappa = 0$ (minimal coupling) is assumed, the limit becomes $M_{LQ} > 1710$ GeV. See their Fig. 10 for exclusion contour in B($b\mu$)−M_{LQ} plane.

[9] AAD 23F search for $\kappa = 1$ (YM coupling) vector leptoquarks decaying to $t\nu$ and be in pp collisions at $\sqrt{s} = 13$ TeV. If $\kappa = 0$ (minimal coupling) is assumed, the limit becomes $M_{LQ} > 1620$ GeV. See their Fig. 10 for exclusion contour in B(be)−M_{LQ} plane.

[10] TUMASYAN 22H search for scalar leptoquarks decaying to te. See their Fig. 27 for exclusion limit on leptoquark pair production cross section as function of M_{LQ}.

[11] TUMASYAN 22H search for scalar leptoquarks decaying to $t\mu$. See their Fig. 27 for exclusion limit on leptoquark pair production cross section as function of M_{LQ}.

[12] TUMASYAN 22H search for scalar leptoquarks decaying to $t\tau$. See their Fig. 27 for exclusion limit on leptoquark pair production cross section as function of M_{LQ}.

[13] AAD 21AG search for scalar leptoquarks decaying to te. See their Fig. 6 for exclusion limit on B(te) as function of M_{LQ}.

[14] AAD 21AG search for scalar leptoquarks decaying to $t\mu$. See their Fig. 6 for exclusion limit on B($t\mu$) as function of M_{LQ}.

[15] AAD 21AW search for scalar leptoquarks decaying to $b\tau$. See their Fig. 9 for exclusion contour in B($b\tau$)−M_{LQ} plane.

[16] AAD 21AW search for scalar leptoquarks decaying to $t\tau$. See their Fig. 9 for exclusion contour in B($t\tau$)−M_{LQ} plane.

[17] AAD 21AW search for $\kappa = 1$ vector leptoquarks decaying to $b\tau$. See their Fig. 10 for exclusion contour in B($b\tau$)−M_{LQ} plane and for limit on $\kappa = 0$ vector leptoquarks.

[18] AAD 21S search for scalar leptoquarks decaying to $b\nu$ in pp collisions at $\sqrt{s} = 13$ TeV. The limit above assumes B($b\nu$) = 1. For B($b\nu$) = 0.05, the limit becomes 400 GeV.

[19] AAD 21T search for scalar leptoquarks decaying to $t\tau$ in pp collisions at $\sqrt{s} = 13$ TeV. The limit above assumes B($t\tau$) = 1. For B($t\tau$) = 0.5, the limit becomes 1220 GeV. See their Fig. 15b for limits on B($t\tau$) as a function of leptoquark mass.

[20] SIRUNYAN 21J search for scalar leptoquarks decaying to $t\tau$ and $b\nu$ in pp collisions at $\sqrt{s} = 13$ TeV.

[21] SIRUNYAN 21J search for vector leptoquarks decaying to $t\nu$ and $b\tau$ in pp collisions at $\sqrt{s} = 13$ TeV. The limit quoted above assumes $\kappa = 1$. If we assume $\kappa = 0$, the limit becomes $M_{LQ} > 1290$ GeV.

[22] AAD 20AK search for scalar leptoquarks decaying to eq, eb, ec, μq, μb, μc. The quoted limit assumes B(eq) = 1. See their Fig. 9 for limits on B(eq), B(eb), B(ec), B(μq), B(μb), B(μc) as a function of leptoquark mass.

[23] AAD 20AK search for scalar leptoquarks decaying to eq, eb, ec, μq, μb, μc. The quoted limit assumes B(μq) = 1. See their Fig. 9 for limits on B(eq), B(eb), B(ec), B(μq), B(μb), B(μc) as a function of leptoquark mass.

[24] AAD 20S search for scalar leptoquarks decaying to $t\nu$ in pp collisions at $\sqrt{s} = 13$ TeV.

[25] SIRUNYAN 20A search for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$ (q = u, d, s, c). The limit quoted above assumes scalar leptoquark with B(νb) = 1.

[26] SIRUNYAN 20A search for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$ (q = u, d, s, c). The limit quoted above assumes scalar leptoquark with B(νt) = 1.

[27] SIRUNYAN 20A search for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$ (q = u, d, s, c). The limit quoted above assumes scalar leptoquark with B(νq) = 1.

[28] SIRUNYAN 20A search for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$ (q = u, d, s, c). The limit quoted above assumes vector leptoquark with B(νb) = 1 and $\kappa = 1$. If we assume $\kappa = 0$, the limit becomes $M_{LQ} > 1560$ GeV.

[29] SIRUNYAN 20A search for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$ (q = u, d, s, c). The limit quoted above assumes vector leptoquark with B(νt) = 1 and $\kappa = 1$. If we assume $\kappa = 0$, the limit becomes $M_{LQ} > 1475$ GeV.

[30] SIRUNYAN 20A search for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$ (q = u, d, s, c). The limit quoted above assumes vector leptoquark with B(νq) = 1 and $\kappa = 1$. If we assume $\kappa = 0$, the limit becomes $M_{LQ} > 1560$ GeV.

[31] AABOUD 19AX search for leptoquarks using $eejj$ events in pp collisions at $\sqrt{s} = 13$ TeV. The limit above assumes B(eq) = 1.

[32] AABOUD 19AX search for leptoquarks using $\mu\mu jj$ events in pp collisions at $\sqrt{s} = 13$ TeV. The limit above assumes B(μq) = 1.

[33] AABOUD 19X search for scalar leptoquarks decaying to $t\nu$ in pp collisions at $\sqrt{s} = 13$ TeV.

[34] AABOUD 19X search for scalar leptoquarks decaying to $b\tau$ in pp collisions at $\sqrt{s} = 13$ TeV.

[35] AABOUD 19X search for scalar leptoquarks decaying to $b\nu$ in pp collisions at $\sqrt{s} = 13$ TeV.

[36] AABOUD 19X search for scalar leptoquarks decaying to $t\tau$ in pp collisions at $\sqrt{s} = 13$ TeV.

[37] SIRUNYAN 19BI search for a pair of scalar leptoquarks decaying to $\mu\mu jj$ and to $\mu\nu jj$ final states in pp collisions at $\sqrt{s} = 13$ TeV. Limits are shown as a function of β where β is the branching fraction to a muon and a quark. For $\beta = 1.0$ (0.5) LQ masses up to 1530 (1285) GeV are excluded. See Fig. 9 for exclusion limits in the plane of β and LQ mass.

[38] SIRUNYAN 19BJ search for a pair of scalar leptoquarks decaying to $eejj$ and $e\nu jj$ final states in pp collisions at $\sqrt{s} = 13$ TeV. Limits are shown as a function of the branching fraction β to an electron and a quark. For $\beta = 1.0$ (0.5) LQ masses up to 1435 (1270) GeV are excluded. See Fig. 9 for exclusion limits in the plane of β and LQ mass.

[39] SIRUNYAN 19Y search for a pair of third generation scalar leptoquarks, each decaying to τ and a jet. Assuming B(τb) = 1, leptoquark masses below 1.02 TeV are excluded.

[40] SIRUNYAN 18CZ search for scalar leptoquarks decaying to τt in pp collisions at $\sqrt{s} =$ 13 TeV. The limit above assumes B(τt) = 1.

[41] SIRUNYAN 18EC set limits for scalar and vector leptoquarks decaying to μt, τt, and νb. The limit quoted above assumes scalar leptoquark with B(μt) = 1.

[42] SIRUNYAN 18EC set limits for scalar and vector leptoquarks decaying to μt, τt, and νb. The limit quoted above assumes vector leptoquark with all possible combinations of branching fractions to μt, τt, and νb.

[43] SIRUNYAN 18U set limits for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$. The limit quoted above assumes scalar leptoquark with B($b\nu$) = 1. Vector leptoquarks with $\kappa = 1$ are excluded below masses of 1810 GeV.

[44] SIRUNYAN 18U set limits for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$. The limit quoted above assumes scalar leptoquark with B($q\nu$) = 1. Vector leptoquarks with $\kappa = 1$ are excluded below masses of 1790 GeV.

[45] SIRUNYAN 18U set limits for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$. The limit quoted above assumes scalar leptoquark with B(νt) = 1. Vector leptoquarks with $\kappa = 1$ are excluded below masses of 1780 GeV.

[46] SIRUNYAN 18U set limits for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$. $\kappa = 1$ and LQ→ $b\nu$ are assumed.

[47] SIRUNYAN 18U set limits for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$. $\kappa = 1$ and LQ→ $q\nu$ with q = u,d,s,c are assumed.

[48] SIRUNYAN 18U set limits for scalar and vector leptoquarks decaying to $t\nu$, $b\nu$, and $q\nu$. $\kappa = 1$ and LQ→ $t\nu$ are assumed.

[49] KHACHATRYAN 17J search for scalar leptoquarks decaying to τb using pp collisions at $\sqrt{s} = 13$ TeV. The limit above assumes B(τb) = 1.

[50] SIRUNYAN 17H search for scalar leptoquarks using $\tau\tau bb$ events in pp collisions at $\sqrt{s}$ = 8 TeV. The limit above assumes B(τb) = 1.

[51] AAD 16G search for scalar leptoquarks using $eejj$ events in collisions at $\sqrt{s} = 8$ TeV. The limit above assumes $B(eq) = 1$.

[52] AAD 16G search for scalar leptoquarks using $\mu\mu jj$ events in collisions at $\sqrt{s} = 8$ TeV. The limit above assumes $B(\mu q) = 1$.

[53] AAD 16G search for scalar leptoquarks decaying to $b\nu$. The limit above assumes $B(b\nu)$ = 1.

[54] AAD 16G search for scalar leptoquarks decaying to $t\nu$. The limit above assumes $B(t\nu)$ = 1.

[55] KHACHATRYAN 16AF search for scalar leptoquarks using $eejj$ and $e\nu jj$ events in pp collisions at $\sqrt{s} = 8$ TeV. The limit above assumes B(eq)= 1. For B(eq) = 0.5, the limit becomes 850 GeV.

[56] KHACHATRYAN 16AF search for scalar leptoquarks using $\mu\mu jj$ and $\mu\nu jj$ events in pp collisions at $\sqrt{s} = 8$ TeV. The limit above assumes B(μq) = 1. For B(μq) = 0.5, the limit becomes 760 GeV.

[57] KHACHATRYAN 15AJ search for scalar leptoquarks using $\tau\tau tt$ events in pp collisions at $\sqrt{s} = 8$ TeV. The limit above assumes $B(\tau t) = 1$.

[58] KHACHATRYAN 14T search for scalar leptoquarks decaying to τb using pp collisions at $\sqrt{s} = 8$ TeV. The limit above assumes B(τb) = 1. See their Fig. 5 for the exclusion limit as function of B(τb).

[59] SIRUNYAN 19BC search for scalar leptoquark (LQ) pair production in pp collisions at $\sqrt{s} = 13$ TeV. One LQ is assumed to decay to μq, while the other decays to dark matter pair and SM particles. See their Fig. 4 for limits in M_{LQ}−M_{DM} plane.

[60] AAD 13AE search for scalar leptoquarks using $\tau\tau bb$ events in pp collisions at E_{cm} = 7 TeV. The limit above assumes B(τb) = 1.

[61] CHATRCHYAN 13M search for scalar and vector leptoquarks decaying to τb in pp collisions at $E_{\mathrm{cm}} = 7$ TeV. The limit above is for scalar leptoquarks with B(τb) = 1.

[62] AAD 12H search for scalar leptoquarks using $eejj$ and $e\nu jj$ events in pp collisions at $E_{\mathrm{cm}} = 7$ TeV. The limit above assumes B(eq) = 1. For B(eq) = 0.5, the limit becomes 607 GeV.

[63] AAD 12O search for scalar leptoquarks using $\mu\mu jj$ and $\mu\nu jj$ events in pp collisions at $E_{\mathrm{cm}} = 7$ TeV. The limit above assumes B(μq) = 1. For B(μq) = 0.5, the limit becomes 594 GeV.

[64] CHATRCHYAN 12AG search for scalar leptoquarks using $eejj$ and $e\nu jj$ events in pp collisions at $E_{\mathrm{cm}} = 7$ TeV. The limit above assumes B(eq) = 1. For B(eq) = 0.5, the limit becomes 640 GeV.

[65] CHATRCHYAN 12AG search for scalar leptoquarks using $\mu\mu jj$ and $\mu\nu jj$ events in pp collisions at $E_{\mathrm{cm}} = 7$ TeV. The limit above assumes B(μq) = 1. For B(μq) = 0.5, the limit becomes 650 GeV.

[66] CHATRCHYAN 12BO search for scalar leptoquarks decaying to νb in pp collisions at $\sqrt{s}$ = 7 TeV. The limit above assumes B(νb) = 1.

[67] AAD 11D search for scalar leptoquarks using $eejj$ and $e\nu jj$ events in pp collisions at $E_{\mathrm{cm}} = 7$ TeV.The limit above assumes B(eq) = 1. For B(eq) = 0.5, the limit becomes 319 GeV.

[68] AAD 11D search for scalar leptoquarks using $\mu\mu jj$ and $\mu\nu jj$ events in pp collisions at $E_{\mathrm{cm}} = 7$ TeV. The limit above assumes B(μq) = 1. For B(μq) = 0.5, the limit becomes 362 GeV.

[69] ABAZOV 11V search for scalar leptoquarks using $e\nu jj$ events in $p\overline{p}$ collisions at E_{cm} = 1.96 TeV. The limit above assumes B(eq) = 0.5.

[70] CHATRCHYAN 11N search for scalar leptoquarks using $e\nu jj$ events in pp collisions at $E_{\mathrm{cm}} = 7$ TeV. The limit above assumes B(eq) = 0.5.

[71] KHACHATRYAN 11D search for scalar leptoquarks using $eejj$ events in pp collisions at $E_{\mathrm{cm}} = 7$ TeV. The limit above assumes B(eq) = 1.

[72] KHACHATRYAN 11E search for scalar leptoquarks using $\mu\mu jj$ events in pp collisions at $E_{\mathrm{cm}} = 7$ TeV. The limit above assumes B(μq) = 1.

[73] ABAZOV 10L search for pair productions of scalar leptoquark state decaying to νb in $p\overline{p}$ collisions at $E_{\mathrm{cm}} = 1.96$ TeV. The limit above assumes B(νb) = 1.

[74] ABAZOV 09 search for scalar leptoquarks using $\mu\mu jj$ and $\mu\nu jj$ events in $p\overline{p}$ collisions at $E_{\mathrm{cm}} = 1.96$ TeV. The limit above assumes B(μq) = 1. For B(μq) = 0.5, the limit becomes 270 GeV.

[75] ABAZOV 09AF search for scalar leptoquarks using $eejj$ and $e\nu jj$ events in $p\overline{p}$ collisions at $E_{\mathrm{cm}} = 1.96$ TeV. The limit above assumes B(eq) = 1. For B(eq) = 0.5 the bound becomes 284 GeV.

[76] AALTONEN 08P search for vector leptoquarks using $\tau^+\tau^- b\overline{b}$ events in $p\overline{p}$ collisions at $E_{\mathrm{cm}} = 1.96$ TeV. Assuming Yang-Mills (minimal) couplings, the mass limit is >317 GeV (251 GeV) at 95% CL for B(τb) = 1.

[77] Search for pair production of scalar leptoquark state decaying to τb in $p\overline{p}$ collisions at $E_{\rm cm}$= 1.96 TeV. The limit above assumes B(τb) = 1.

[78] Search for scalar leptoquarks using $\nu\nu jj$ events in $\overline{p}p$ collisions at $E_{\rm cm}$ = 1.96 TeV. The limit above assumes B(νq) = 1.

[79] ABAZOV 07J search for pair productions of scalar leptoquark state decaying to νb in $p\overline{p}$ collisions at $E_{\rm cm}$ = 1.96 TeV. The limit above assumes B(νb) = 1.

[80] ABAZOV 06A search for scalar leptoquarks using $\mu\mu jj$ events in $p\overline{p}$ collisions at $E_{\rm cm}$ = 1.8 TeV and 1.96 TeV. The limit above assumes B(μq) = 1. For B(μq) = 0.5, the limit becomes 204 GeV.

[81] ABAZOV 06L search for scalar leptoquarks using $\nu\nu jj$ events in $p\overline{p}$ collisions at $E_{\rm cm}$ = 1.8 TeV and at 1.96 TeV. The limit above assumes B(νq) = 1.

[82] ABULENCIA 06T search for scalar leptoquarks using $\mu\mu jj$, $\mu\nu jj$, and $\nu\nu jj$ events in $p\overline{p}$ collisions at $E_{\rm cm}$ = 1.96 TeV. The quoted limit assumes B(μq) = 1. For B(μq) = 0.5 or 0.1, the bound becomes 208 GeV or 143 GeV, respectively. See their Fig. 4 for the exclusion limit as a function of B(μq).

[83] ABAZOV 05H search for scalar leptoquarks using $eejj$ and $e\nu jj$ events in $\overline{p}p$ collisions at $E_{\rm cm}$ = 1.8 TeV and 1.96 TeV. The limit above assumes B(eq) = 1. For B(eq) = 0.5 the bound becomes 234 GeV.

[84] ACOSTA 05P search for scalar leptoquarks using $eejj$, $e\nu jj$ events in $\overline{p}p$ collisions at $E_{\rm cm}$ = 1.96TeV. The limit above assumes B(eq) = 1. For B(eq) = 0.5 and 0.1, the bound becomes 205 GeV and 145 GeV, respectively.

[85] ABBIENDI 03R search for scalar/vector leptoquarks in e^+e^- collisions at $\sqrt{s}$ = 189–209 GeV. The quoted limits are for charge $-4/3$ isospin 0 scalar-leptoquark with B(ℓq) = 1. See their table 12 for other cases.

[86] ABAZOV 02 search for scalar leptoquarks using $\nu\nu jj$ events in $\overline{p}p$ collisions at $E_{\rm cm}$=1.8 TeV. The bound holds for all leptoquark generations. Vector leptoquarks are likewise constrained to lie above 200 GeV.

[87] ABAZOV 01D search for scalar leptoquarks using $e\nu jj$, $eejj$, and $\nu\nu jj$ events in $p\overline{p}$ collisions at $E_{\rm cm}$=1.8 TeV. The limit above assumes B(eq)=1. For B(eq)=0.5 and 0, the bound becomes 204 and 79 GeV, respectively. Bounds for vector leptoquarks are also given. Supersedes ABBOTT 98E.

[88] ABBIENDI 00M search for scalar/vector leptoquarks in e^+e^- collisions at $\sqrt{s}$=183 GeV. The quoted limits are for charge $-4/3$ isospin 0 scalar-leptoquarks with B(ℓq)=1. See their Table 8 and Figs. 6–9 for other cases.

[89] ABBOTT 00C search for scalar leptoquarks using $\mu\mu jj$, $\mu\nu jj$, and $\nu\nu jj$ events in $p\overline{p}$ collisions at $E_{\rm cm}$=1.8 TeV. The limit above assumes B(μq)=1. For B(μq)=0.5 and 0, the bound becomes 180 and 79 GeV respectively. Bounds for vector leptoquarks are also given.

[90] AFFOLDER 00K search for scalar leptoquark using $\nu\nu cc$ events in $p\overline{p}$ collisions at $E_{\rm cm}$=1.8 TeV. The quoted limit assumes B(νc)=1. Bounds for vector leptoquarks are also given.

[91] AFFOLDER 00K search for scalar leptoquark using $\nu\nu bb$ events in $p\overline{p}$ collisions at $E_{\rm cm}$=1.8 TeV. The quoted limit assumes B(νb)=1. Bounds for vector leptoquarks are also given.

[92] ABBOTT 99J search for leptoquarks using $\mu\nu jj$ events in $p\overline{p}$ collisions at $E_{\rm cm}$= 1.8TeV. The quoted limit is for a scalar leptoquark with B(μq) = B(νq) = 0.5. Limits on vector leptoquarks range from 240 to 290 GeV.

[93] ABBOTT 98E search for scalar leptoquarks using $e\nu jj$, $eejj$, and $\nu\nu jj$ events in $p\overline{p}$ collisions at $E_{\rm cm}$=1.8 TeV. The limit above assumes B(eq)=1. For B(eq)=0.5 and 0, the bound becomes 204 and 79 GeV, respectively.

[94] ABBOTT 98J search for charge $-1/3$ third generation scalar and vector leptoquarks in $p\overline{p}$ collisions at $E_{\rm cm}$= 1.8 TeV. The quoted limit is for scalar leptoquark with B(νb)=1.

[95] ABE 98S search for scalar leptoquarks using $\mu\mu jj$ events in $p\overline{p}$ collisions at $E_{\rm cm}$= 1.8 TeV. The limit is for B(μq)= 1. For B(μq)=B(νq)=0.5, the limit is $>$ 160 GeV.

[96] GROSS-PILCHER 98 is the combined limit of the CDF and DØ Collaborations as determined by a joint CDF/DØ working group and reported in this FNAL Technical Memo. Original data published in ABE 97X and ABBOTT 98E.

[97] ABE 97F search for third generation scalar and vector leptoquarks in $p\overline{p}$ collisions at $E_{\rm cm}$ = 1.8 TeV. The quoted limit is for scalar leptoquark with B(τb) = 1.

[98] ABE 97X search for scalar leptoquarks using $eejj$ events in $p\overline{p}$ collisions at $E_{\rm cm}$=1.8 TeV. The limit is for B(eq)=1.

[99] Limit is for charge $-1/3$ isospin-0 leptoquark with B(ℓq) = 2/3.

[100] First and second generation leptoquarks are assumed to be degenerate. The limit is slightly lower for each generation.

[101] Limits are for charge $-1/3$, isospin-0 scalar leptoquarks decaying to $\ell^- q$ or νq with any branching ratio. See paper for limits for other charge-isospin assignments of leptoquarks.

[102] KIM 90 assume pair production of charge 2/3 scalar-leptoquark via photon exchange. The decay of the first (second) generation leptoquark is assumed to be any mixture of de^+ and $u\overline{\nu}$ ($s\mu^+$ and $c\overline{\nu}$). See paper for limits for specific branching ratios.

[103] BARTEL 87B limit is valid when a pair of charge 2/3 spinless leptoquarks X is produced with point coupling, and when they decay under the constraint B($X \to c\overline{\nu}_\mu$) + B($X \to s\mu^+$) = 1.

[104] BEHREND 86B assumed that a charge 2/3 spinless leptoquark, χ, decays either into $s\mu^+$ or $c\overline{\nu}$: B($\chi \to s\mu^+$) + B($\chi \to c\overline{\nu}$) = 1.

MASS LIMITS for Leptoquarks from Single Production

These limits depend on the q-ℓ-leptoquark coupling g_{LQ}. It is often assumed that $g^2_{LQ}/4\pi$=1/137. Limits shown are for a scalar, weak isoscalar, charge $-1/3$ leptoquark.

[1] AAD 23BZ search for single production of charge 4/3 scalar leptoquarks decaying to $b\tau^-$, and charge 2/3 vector leptoquarks decaying to $\overline{b}\tau^-$ in pp collisions at $\sqrt{s}$ = 13 TeV. The limit quoted above assumes a scalar leptoquark with B($b\tau$) = 1 and the leptoquark coupling strength λ = 1.0. The limit becomes M_{LQ} > 1530 GeV for λ = 2.5.

[2] SIRUNYAN 21J search for single production of charge $-1/3$ scalar leptoquarks decaying to $t\tau^-$ and $b\nu$, and charge 2/3 vector leptoquarks decaying to $t\nu$ and $b\tau^+$ in pp collisions at $\sqrt{s}$ = 13 TeV. The limit quoted above assumes a scalar leptoquark with B($t\tau$) = B($b\nu$) = 0.5 and the leptoquark coupling strength λ = 1.5. The limit becomes M_{LQ} > 750 GeV for λ = 2.5.

[3] SIRUNYAN 18BJ search for single production of charge 2/3 scalar leptoquarks decaying to τb in pp collisions at $\sqrt{s}$ = 13 TeV. The limit above assumes B(τb) = 1 and the leptoquark coupling strength λ = 1.

[4] KHACHATRYAN 16AG search for single production of charge $\pm 1/3$ scalar leptoquarks using eej events in pp collisions at $\sqrt{s}$ = 8 TeV. The limit above assumes B(eq) = 1 and the leptoquark coupling strength λ = 1.

[5] KHACHATRYAN 16AG search for single production of charge $\pm 1/3$ scalar leptoquarks using $\mu\mu j$ events in pp collisions at $\sqrt{s}$ = 8 TeV. The limit above assumes B(μq) = 1 and the leptoquark coupling strength λ = 1.

[6] ABRAMOWICZ 12A limit is for a scalar, weak isoscalar, charge $-1/3$ leptoquark coupled with e_R. See their Figs. 12–17 and Table 4 for states with different quantum numbers.

[7] Limit from single production in Z decay. The limit is for a leptoquark coupling of electromagnetic strength and assumes B(ℓq) = 2/3. The limit is 77 GeV if first and second leptoquarks are degenerate.

[8] AAD 22E leptoquarks decaying both to ue^- and $c\mu^-$ are constrained from the comparison of the production cross sections for $e^+\mu^-$ and $e^-\mu^+$ in pp collisions at $\sqrt{s}$ = 13 TeV. Scalar leptoquarks with M_{LQ} < 1880 GeV are excluded for $g^{eu} = g^{\mu c} = 1$.

[9] TUMASYAN 21D search for energetic jets + $\not{E}_T$ events in pp collisions at $\sqrt{s}$ = 13 TeV. The branching fraction for the decay of the leptoquark into an electron neutrino and up quark is assumed to be 100% (β = 0). See their Fig. 12 for exclusion limits in mass-coupling plane.

[10] DEY 16 use the 2010-2012 IceCube PeV energy data set to constrain the leptoquark production cross section through the $\nu q \to$ LQ $\to \nu q$ process. See their Figure 4 for the exclusion limit in the mass-coupling plane.

[11] AARON 11A search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 2–3 and Tables 1–4 for detailed limits.

[12] The quoted limit is for a scalar, weak isoscalar, charge $-1/3$ leptoquark coupled with e_R. See their Figs. 3–5 for limits on states with different quantum numbers.

[13] ABAZOV 07E search for leptoquark single production through qg fusion process in $p\overline{p}$ collisions. See their Fig. 4 for exclusion plot in mass-coupling plane.

[14] AKTAS 05B limit is for a scalar, weak isoscalar, charge $-1/3$ leptoquark coupled with e_R. See their Fig. 3 for limits on states with different quantum numbers.

[15] CHEKANOV 05 search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 6–10 and Tables 1–8 for detailed limits.

[16] CHEKANOV 03B limit is for a scalar, weak isoscalar, charge $-1/3$ leptoquark coupled with e_R. See their Figs. 11–12 and Table 5 for limits on states with different quantum numbers.

[17] For limits on states with different quantum numbers and the limits in the mass-coupling plane, see their Fig. 4 and Fig. 5.

[18] CHEKANOV 02 search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 6–7 and Tables 5–6 for detailed limits.

[19] For limits on states with different quantum numbers and the limits in the mass-coupling plane, see their Fig. 3.

[20] See their Fig. 14 for limits in the mass-coupling plane.

[21] BREITWEG 00E search for F=0 leptoquarks in e^+p collisions. For limits in mass-coupling plane, see their Fig. 11.

[22] ABREU 99G limit obtained from process $e\gamma \to LQ+q$. For limits on vector and scalar states with different quantum numbers and the limits in the coupling-mass plane, see their Fig. 4 and Table 2.

[23] For limits on states with different quantum numbers and the limits in the mass-coupling plane, see their Fig. 13 and Fig. 14. ADLOFF 99 also search for leptoquarks with lepton-flavor violating couplings. ADLOFF 99 supersedes AID 96B.

[24] DERRICK 97 search for various leptoquarks with lepton-flavor violating couplings. See their Figs. 5–8 and Table 1 for detailed limits.

[25] DERRICK 93 search for single leptoquark production in ep collisions with the decay eq and νq. The limit is for leptoquark coupling of electromagnetic strength and assumes B(eq) = B(νq) = 1/2. The limit for B(eq) = 1 is 176 GeV. For limits on states with different quantum numbers, see their Table 3.

[1] CALABRESE 23 obtain limits on leptoquark coupling from coherent ν-nucleus scattering data collected by COHERENT experiment. See their Fig. 3 for limits in mass-coupling plane.

[2] TUMASYAN 23AW search for $\tau\nu$ events mediated by t-channel leptoquark exchange in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 10 for limits in mass-coupling plane.

[3] TUMASYAN 23S search for leptoquark induced $b\overline{b} \to \tau^+\tau^-$ process in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 12 for limits on a vector $b\tau$ leptoquark in mass-coupling plane.

[4] CRIVELLIN 21A set limits on coupling strengths of scalar and vector leptoquarks using $K \to \pi\nu\nu$, $K \to \pi e^+e^-$, $K^0 - \overline{K}^0$ and $D^0 - \overline{D}^0$ mixings, and weak neutral current measurements. See their Fig. 2 and Fig. 3 for the limits in mass-coupling plane.

[5] AEBISCHER 20 explain the B decay anomalies using four-fermion operator Wilson coefficents. See their Table 1. These Wilson coefficients may be generated by a U_1 vector leptoquark with U_1 transforming as $(3,1)_{2/3}$ under the SM gauge group. See their Figures 6, 7, 8 for the regions of the LQ parameter space which explains the B anomalies and avoids the indirect low energy constraints.

[6] DEPPISCH 20 limits on the lepton-number-violating higher-dimensional-operators are derived from $K \to \pi\nu\nu$ in the standard model effective field theory. These higher-dimensional-operators may be induced from leptoquark-exchange diagrams.

[7] ABRAMOWICZ 19 obtain a limit on $\lambda/M_{LQ} > 1.16$ TeV^{-1} for weak isotriplet spin-0 leptoquark S_1^L. We obtain the limit quoted above by converting the limit on λ/M_{LQ} for S_1^L assuming $\lambda = \sqrt{4\pi}$. See their Table 5 for the limits of leptoquarks with different quantum numbers. These limits are derived from bounds of eq contact interactions.

[8] MANDAL 19 give bounds on leptoquarks from τ-decays, leptonic dipole moments, lepton-flavor-violating processes, and K decays.

[9] ZHANG 18A give bounds on leptoquark induced four-fermion interactions from $D \to K\ell\nu$. The authors inform us that the shape parameter of the vector form factor in both the abstract and the conclusions of ZHANG 18A should be $r_{+1} = 2.16 \pm 0.07$ rather than ± 0.007. The numbers listed in their Table 7 are correct.

[10] BARRANCO 16 give bounds on leptoquark induced four-fermion interactions from $D \to K\ell\nu$ and $D_s \to \ell\nu$.

[11] KUMAR 16 gives bound on SU(2) singlet scalar leptoquark with chrge $-1/3$ from $K^0 - \overline{K}^0$ mixing, $K \to \pi\nu\overline{\nu}$, $K_L^0 \to \mu^+\mu^-$, and $K_L^0 \to \mu^\pm e^\mp$ decays.

[12] BESSAA 15 obtain limit on leptoquark induced four-fermion interactions from the ATLAS and CMS limit on the $\overline{q}q\overline{e}e$ contact interactions.

[13] SAHOO 15A obtain limit on leptoquark induced four-fermion interactions from $B_{s,d} \to \mu^+\mu^-$ for $\lambda \simeq O(1)$.

[14] SAKAKI 13 explain the $B \to D^{(*)}\tau\overline{\nu}$ anomaly using Wilson coefficients of leptoquark-induced four-fermion operators.

[15] KOSNIK 12 obtains limits on leptoquark induced four-fermion interactions from $b \to s\ell^+\ell^-$ decays.

[16] AARON 11C limit is for weak isotriplet spin-0 leptoquark at strong coupling $\lambda = \sqrt{4\pi}$. For the limits of leptoquarks with different quantum numbers, see their Table 3. Limits are derived from bounds of eq contact intereactions.

[17] DORSNER 11 give bounds on scalar, weak singlet, charge 4/3 leptoquark from K, B, τ decays, meson mixings, LFV, $g-2$ and $Z \to b\overline{b}$.

[18] AKTAS 07A search for lepton-flavor violation in ep collision. See their Tables 4–7 for limits on lepton-flavor violating four-fermion interactions induced by various leptoquarks.

[19] SCHAEL 07A limit is for the weak-isoscalar spin-0 left-handed leptoquark with the coupling of electromagnetic strength. For the limits of leptoquarks with different quantum numbers, see their Table 35.

[20] SMIRNOV 07 obtains mass limits for the vector and scalar chiral leptoquark states from $K \to e\mu$, $B \to e\tau$ decays.

[21] CHEKANOV 05 search for various leptoquarks with lepton-flavor violating couplings. See their Figs.6–10 and Tables 1–8 for detailed limits.

[22] ADLOFF 03 limit is for the weak isotriplet spin-0 leptoquark at strong coupling $\lambda = \sqrt{4\pi}$. For the limits of leptoquarks with different quantum numbers, see their Table 3. Limits are derived from bounds on $e^\pm q$ contact interactions.

[23] The bound is derived from B($B^0 \to e^\pm\mu^\mp$) $< 1.7 \times 10^{-7}$.

[24] CHEKANOV 02 search for lepton-flavor violation in ep collisions. See their Tables 1–4 for limits on lepton-flavor violating and four-fermion interactions induced by various leptoquarks.

[25] CHEUNG 01B quoted limit is for a scalar, weak isoscalar, charge $-1/3$ leptoquark with a coupling of electromagnetic strength. The limit is derived from bounds on contact interactions in a global electroweak analysis. For the limits of leptoquarks with different quantum numbers, see Table 5.

[26] ACCIARRI 00P limit is for the weak isoscalar spin-0 leptoquark with the coupling of electromagnetic strength. For the limits of leptoquarks with different quantum numbers, see their Table 4.

[27] ADLOFF 00 limit is for the weak isotriplet spin-0 leptoquark at strong coupling, $\lambda = \sqrt{4\pi}$. For the limits of leptoquarks with different quantum numbers, see their Table 2. ADLOFF 00 limits are from the Q^2 spectrum measurement of $e^+p \to e^+$X.

[28] BARATE 00I search for deviations in cross section and jet-charge asymmetry in $e^+e^- \to \overline{q}q$ due to t-channel exchange of a leptoquark at $\sqrt{s}$=130 to 183 GeV. Limits for other scalar and vector leptoquarks are also given in their Table 22.

[29] BARGER 00 explain the deviation of atomic parity violation in cesium atoms from prediction is explained by scalar leptoquark exchange.

[30] GABRIELLI 00 calculate various process with lepton flavor violation in leptoquark models.

[31] ZARNECKI 00 limit is derived from data of HERA, LEP, and Tevatron and from various low-energy data including atomic parity violation. Leptoquark coupling with electromagnetic strength is assumed.

[32] ABBIENDI 99 limits are from $e^+e^- \to q\overline{q}$ cross section at 130–136, 161–172, 183 GeV. See their Fig. 8 and Fig. 9 for limits in mass-coupling plane.

[33] ABE 98V quoted limit is from B($B_s \to e^\pm\mu^\mp$)$< 8.2 \times 10^{-6}$. ABE 98V also obtain a similar limit on $M_{LQ} > 20.4$ TeV from B($B_d \to e^\pm\mu^\mp$)$< 4.5 \times 10^{-6}$. Both bounds assume the non-canonical association of the b quark with electrons or muons under SU(4).

[34] ACCIARRI 98J limit is from $e^+e^- \to q\overline{q}$ cross section at $\sqrt{s}$= 130–172 GeV which can be affected by the t- and u-channel exchanges of leptoquarks. See their Fig. 4 and Fig. 5 for limits in the mass-coupling plane.

[35] ACKERSTAFF 98V limits are from $e^+e^- \to q\overline{q}$ and $e^+e^- \to b\overline{b}$ cross sections at $\sqrt{s}$ = 130–172 GeV, which can be affected by the t- and u-channel exchanges of leptoquarks. See their Fig. 21 and Fig. 22 for limits of leptoquarks in mass-coupling plane.

[36] DEANDREA 97 limit is for $\tilde{R}_2$ leptoquark obtained from atomic parity violation (APV). The coupling of leptoquark is assumed to be electromagnetic strength. See Table 2 for limits of the four-fermion interactions induced by various scalar leptoquark exchange. DEANDREA 97 combines APV limit and limits from Tevatron and HERA. See Fig. 1–4 for combined limits of leptoquark in mass-coupling plane.

[37] DERRICK 97 search for lepton-flavor violation in ep collision. See their Tables 2–5 for limits on lepton-flavor violating four-fermion interactions induced by various leptoquarks.

[38] GROSSMAN 97 estimate the upper bounds on the branching fraction $B \to \tau^+\tau^-$(X) from the absence of the B decay with large missing energy. These bounds can be used to constrain leptoquark induced four-fermion interactions.

[39] JADACH 97 limit is from $e^+e^- \to q\overline{q}$ cross section at $\sqrt{s}$=172.3 GeV which can be affected by the t- and u-channel exchanges of leptoquarks. See their Fig. 1 for limits on vector leptoquarks in mass-coupling plane.

[40] KUZNETSOV 95B use π, K, B, τ decays and μe conversion and give a list of bounds on the leptoquark mass and the fermion mixing matrix in the Pati-Salam model. The quoted limit is from $K_L \to \mu e$ decay assuming zero mixing.

[41] MIZUKOSHI 95 calculate the one-loop radiative correction to the Z-physics parameters in various scalar leptoquark models. See their Fig. 4 for the exclusion plot of third generation leptoquark models in mass-coupling plane.

[42] BHATTACHARYYA 94 limit is from one-loop radiative correction to the leptonic decay width of the Z. m_H=250 GeV, $\alpha_s(m_Z)$=0.12, m_t=180 GeV, and the electroweak strength of leptoquark coupling are assumed. For leptoquark coupled to $\overline{e}_L\, t_R$, $\overline{\mu}t$, and $\overline{\tau}t$, see Fig. 2 in BHATTACHARYYA 94B erratum and Fig. 3.

[43] DAVIDSON 94 gives an extensive list of the bounds on leptoquark-induced four-fermion interactions from π, K, D, B, μ, τ decays and meson mixings, *etc.* See Table 15 of DAVIDSON 94 for detail.

[44] KUZNETSOV 94 gives mixing independent bound of the Pati-Salam leptoquark from the cosmological limit on $\pi^0 \to \overline{\nu}\nu$.

[45] LEURER 94, LEURER 94B limits are obtained from atomic parity violation and apply to any chiral leptoquark which couples to the first generation with electromagnetic strength. For a nonchiral leptoquark, universality in $\pi_{\ell 2}$ decay provides a much more stringent bound.

[46] MAHANTA 94 gives bounds of P- and T-violating scalar-leptoquark couplings from atomic and molecular experiments.

[47] From $(\pi \to e\nu)/(\pi \to \mu\nu)$ ratio. SHANKER 82 assumes the leptoquark induced four-fermion coupling $4g^2/M^2\ (\overline{\nu}_{eL}\ u_R)\ (\overline{d}_L\, e_R)$with g=0.004 for spin-0 leptoquark and $g^2/M^2\ (\overline{\nu}_{eL}\ \gamma_\mu u_L)\ (\overline{d}_R\ \gamma^\mu\, e_R)$ with $g \simeq 0.6$ for spin-1 leptoquark.

[2] KHACHATRYAN 17W search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV.
[3] KHACHATRYAN 16K search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV.
[4] KHACHATRYAN 16L search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 8$ TeV with the data scouting technique, increasing the sensitivity to the low mass resonances.
[5] KHACHATRYAN 15V search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 8$ TeV.
[6] CHATRCHYAN 13A search for new resonance decaying to dijets in pp collisions at $\sqrt{s} = 7$ TeV.
[7] CHATRCHYAN 13AS search for new resonance decaying to dijets in pp collisions at $\sqrt{s} = 8$ TeV.
[8] CHATRCHYAN 11Y search for new resonance decaying to dijets in pp collisions at $\sqrt{s} = 7$ TeV.
[9] KHACHATRYAN 10 search for new resonance decaying to dijets in pp collisions at $\sqrt{s} = 7$ TeV.
[10] AALTONEN 09AC search for new narrow resonance decaying to dijets.
[11] ABE 97G search for new particle decaying to dijets.
[12] ABREU 94O limit is from $e^+e^- \to \overline{cs}cs$. Range extends up to 43 GeV if diquarks are degenerate in mass.

MASS LIMITS for g_A (axiguon) and Other Color-Octet Gauge Bosons

Axiguons are massive color-octet gauge bosons in chiral color models and have axial-vector coupling to quarks with the same coupling strength as gluons.

[1] SIRUNYAN 20AI search for resonances decaying into dijets in pp collisions at $\sqrt{s} = 13$ TeV.
[2] SIRUNYAN 18BO search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV.
[3] KHACHATRYAN 17W search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV.
[4] KHACHATRYAN 16K search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 13$ TeV.
[5] KHACHATRYAN 16L search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 8$ TeV with the data scouting technique, increasing the sensitivity to the low mass resonances.
[6] KHACHATRYAN 15V search for resonances decaying to dijets in pp collisions at $\sqrt{s} = 8$ TeV.
[7] KHACHATRYAN 17Y search for pair production of color-octet gauge boson g_A each decaying to $4j$ in pp collisions at $\sqrt{s} = 8$ TeV.
[8] AAD 16W search for a new resonance decaying to a pair of b and B_H in pp collisions at $\sqrt{s} = 8$ TeV. The vector-like quark B_H is assumed to decay to bH. See their Fig. 3 and Fig. 4 for limits on $\sigma \cdot B$.
[9] KHACHATRYAN 16E search for KK gluon decaying to $t\overline{t}$ in pp collisions at $\sqrt{s} = 8$ TeV.
[10] KHACHATRYAN 15AV search for pair productions of neutral color-octet weak-triplet scalar particles (Θ^0), decaying to $b\overline{b}$, Zg or γg, in pp collisions at $\sqrt{s} = 8$ TeV. The Θ^0 particle is often predicted in coloron (G', color-octet gauge boson) models and appear in the pp collisions through $G' \to \Theta^0\Theta^0$ decays. Assuming B($\Theta^0 \to b\overline{b}$) = 0.5, they give limits $m_{\Theta^0} > 623$ GeV (426 GeV) for $m_{G'} = 2.3\ m_{\Theta^0}$ ($m_{G'} = 5\ m_{\Theta^0}$).
[11] AALTONEN 13R search for new resonance decaying to $\sigma\sigma$, with hypothetical strongly interacting σ particle subsequently decaying to 2 jets, in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV, using data corresponding to an integrated luminosity of 6.6 fb^{-1}. For 50 GeV $< m_\sigma <$ $m_{g_A}/2$, axigluons in mass range 150–400 GeV are excluded.
[12] CHATRCHYAN 13A search for new resonance decaying to dijets in pp collisions at $\sqrt{s} = 7$ TeV.
[13] CHATRCHYAN 13AS search for new resonance decaying to dijets in pp collisions at $\sqrt{s} = 8$ TeV.
[14] CHATRCHYAN 13AU search for the pair produced color-octet vector bosons decaying to $q\overline{q}$ pairs in pp collisions. The quoted limit is for B($g_A \to q\overline{q}$) = 1.
[15] ABAZOV 12R search for massive color octet vector particle decaying to $t\overline{t}$. The quoted limit assumes g_A couplings with light quarks are suppressed by 0.2.
[16] CHATRCHYAN 11Y search for new resonance decaying to dijets in pp collisions at $\sqrt{s} = 7$ TeV.
[17] AALTONEN 10L search for massive color octet non-chiral vector particle decaying into $t\overline{t}$ pair with mass in the range 400 GeV $<$ M $<$ 800 GeV. See their Fig. 6 for limit in the mass-coupling plane.
[18] KHACHATRYAN 10 search for new resonance decaying to dijets in pp collisions at $\sqrt{s} = 7$ TeV.
[19] AALTONEN 09AC search for new narrow resonance decaying to dijets.
[20] CHOUDHURY 07 limit is from the $t\overline{t}$ production cross section measured at CDF.
[21] DONCHESKI 98 compare α_s derived from low-energy data and that from $\Gamma(Z \to$ hadrons$)/\Gamma(Z \to$ leptons$)$.
[22] ABE 97G search for new particle decaying to dijets.
[23] ABE 95N assume axigluons decaying to quarks in the Standard Model only.
[24] ABE 93G assume $\Gamma(g_A) = N\alpha_s m_{g_A}/6$ with $N = 10$.
[25] CUYPERS 91 compare α_s measured in Υ decay and that from R at PEP/PETRA energies.
[26] ABE 90H assumes $\Gamma(g_A) = N\alpha_s m_{g_A}/6$ with $N = 5$ ($\Gamma(g_A) = 0.09 m_{g_A}$). For $N = 10$, the excluded region is reduced to 120–150 GeV.
[27] ROBINETT 89 result demands partial-wave unitarity of $J = 0$ $t\overline{t} \to t\overline{t}$ scattering amplitude and derives a limit $m_{g_A} > 0.5\ m_t$. Assumes $m_t > 56$ GeV.
[28] ALBAJAR 88B result is from the nonobservation of a peak in two-jet invariant mass distribution. $\Gamma(g_A) < 0.4\ m_{g_A}$ assumed. See also BAGGER 88.
[29] CUYPERS 88 requires $\Gamma(\Upsilon \to g g_A) < \Gamma(\Upsilon \to ggg)$. A similar result is obtained by DONCHESKI 88.
[30] DONCHESKI 88B requires $\Gamma(\Upsilon \to g q\overline{q})/\Gamma(\Upsilon \to ggg) < 0.25$, where the former decay proceeds via axigluon exchange. A more conservative estimate of $<$ 0.5 leads to $m_{g_A} > 21$ GeV.

MASS LIMITS for Color-Octet Scalar Bosons

[1] SIRUNYAN 20AI search for resonances decaying into dijets in pp collisions at $\sqrt{s} = 13$ TeV. The limit above assumes S_{8gg} coupling $k_s^2 = 1/2$.
[2] SIRUNYAN 18BO search for color octet scalar boson produced through gluon fusion process in pp collisions at $\sqrt{s} = 13$ TeV. The limit above assumes S_{8gg} coupling $k_s^2 = 1/2$.
[3] KHACHATRYAN 15AV search for pair productions of neutral color-octet weak-triplet scalar particles (Θ^0), decaying to $b\overline{b}$, Zg or γg, in pp collisions at $\sqrt{s} = 8$ TeV. The Θ^0 particle is often predicted in coloron (G', color-octet gauge boson) models and appear in the pp collisions through $G' \to \Theta^0\Theta^0$ decays. Assuming B($\Theta^0 \to b\overline{b}$) = 0.5, they give limits $m_{\Theta^0} > 623$ GeV (426 GeV) for $m_{G'} = 2.3\ m_{\Theta^0}$ ($m_{G'} = 5\ m_{\Theta^0}$).
[4] AAD 13K search for pair production of color-octet scalar particles in pp collisions at $\sqrt{s} = 7$ TeV. Cross section limits are interpreted as mass limits on scalar partners of a Dirac gluino.

X^0 (Heavy Boson) Searches in Z Decays

Searches for radiative transition of Z to a lighter spin-0 state X^0 decaying to hadrons, a lepton pair, a photon pair, or invisible particles as shown in the comments. The limits are for the product of branching ratios.

[1] RAINBOLT 19 limits are from $B(Z \to \ell^+\ell^-\ell^+\ell^-)$. See their Figs. 5 and 6 for limits in mass-coupling plane.

[2] SIRUNYAN 19AZ search for $pp \to Z \to X^0\mu^+\mu^- \to \mu^+\mu^-\mu^+\mu^-$ events in pp collisions at $\sqrt{s} = 13$ TeV. See their Fig. 5 for limits on $\sigma(pp \to X^0\mu^+\mu^-)\cdot B(X^0 \to \mu^+\mu^-)$.

[3] BARATE 98U obtain limits on $B(Z \to \gamma X^0)B(X^0 \to \ell\overline{\ell}, q\overline{q}, gg, \gamma\gamma, \nu\overline{\nu})$. See their Fig. 17.

[4] See Fig. 4 of ACCIARRI 97Q for the upper limit on $B(Z \to \gamma X^0; E_\gamma > E_{min})$ as a function of E_{min}.

[5] ACTON 93E give $\sigma(e^+e^- \to X^0\gamma)\cdot B(X^0 \to \gamma\gamma) < 0.4$ pb (95%CL) for m_{X^0}=60 ± 2.5 GeV. If the process occurs via s-channel γ exchange, the limit translates to $\Gamma(X^0)\cdot B(X^0 \to \gamma\gamma)^2 < 20$ MeV for $m_{X^0} = 60 \pm 1$ GeV.

[6] ABREU 92D give $\sigma_Z \cdot B(Z \to \gamma X^0) \cdot B(X^0 \to$ hadrons) <(3–10) pb for m_{X^0} = 10–78 GeV. A very similar limit is obtained for spin-1 X^0.

[7] ADRIANI 92F search for isolated γ in hadronic Z decays. The limit $\sigma_Z \cdot B(Z \to \gamma X^0) \cdot B(X^0 \to$ hadrons) <(2–10) pb (95%CL) is given for m_{X^0} = 25–85 GeV.

[8] ACTON 91 searches for $Z \to Z^*X^0$, $Z^* \to e^+e^-$, $\mu^+\mu^-$, or $\nu\overline{\nu}$. Excludes any new scalar X^0 with $m_{X^0} < 9.5$ GeV/c if it has the same coupling to ZZ^* as the MSM Higgs boson.

[9] ACTON 91B limits are for m_{X^0} = 60–85 GeV.

[10] ADEVA 91D limits are for m_{X^0} = 30–89 GeV.

[11] ADEVA 91D limits are for m_{X^0} = 30–86 GeV.

[12] AKRAWY 90J give $\Gamma(Z \to \gamma X^0)\cdot B(X^0 \to$ hadrons) < 1.9 MeV (95%CL) for m_{X^0} = 32–80 GeV. We divide by $\Gamma(Z) = 2.5$ GeV to get product of branching ratios. For nonresonant transitions, the limit is $B(Z \to \gamma q\overline{q}) < 8.2$ MeV assuming three-body phase space distribution.

MASS LIMITS for a Heavy Neutral Boson Coupling to e^+e^-

VALUE (GeV)	CL%	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •					
none 55–61		[1] ODAKA	89	VNS	$\Gamma(X^0 \to e^+e^-)\cdot B(X^0 \to$ had.) $\gtrsim$ 0.2 MeV
>45	95	[2] DERRICK	86	HRS	$\Gamma(X^0 \to e^+e^-)$=6 MeV
>46.6	95	[3] ADEVA	85	MRKJ	$\Gamma(X^0 \to e^+e^-)$=10 keV
>48	95	[3] ADEVA	85	MRKJ	$\Gamma(X^0 \to e^+e^-)$=4 MeV
		[4] BERGER	85B	PLUT	
none 39.8–45.5		[5] ADEVA	84	MRKJ	$\Gamma(X^0 \to e^+e^-)$=10 keV
>47.8	95	[5] ADEVA	84	MRKJ	$\Gamma(X^0 \to e^+e^-)$=4 MeV
none 39.8–45.2		[5] BEHREND	84C	CELL	
>47	95	[5] BEHREND	84C	CELL	$\Gamma(X^0 \to e^+e^-)$=4 MeV

[1] ODAKA 89 looked for a narrow or wide scalar resonance in $e^+e^- \to$ hadrons at E_{cm} = 55.0–60.8 GeV.

[2] DERRICK 86 found no deviation from the Standard Model Bhabha scattering at E_{cm}= 29 GeV and set limits on the possible scalar boson e^+e^- coupling. See their figure 4 for excluded region in the $\Gamma(X^0 \to e^+e^-)$-m_{X^0} plane. Electronic chiral invariance requires a parity doublet of X^0, in which case the limit applies for $\Gamma(X^0 \to e^+e^-)$ = 3 MeV.

[3] ADEVA 85 first limit is from 2γ, $\mu^+\mu^-$, hadrons assuming X^0 is a scalar. Second limit is from e^+e^- channel. E_{cm} = 40–47 GeV. Supersedes ADEVA 84.

[4] BERGER 85B looked for effect of spin-0 boson exchange in $e^+e^- \to e^+e^-$ and $\mu^+\mu^-$ at E_{cm} = 34.7 GeV. See Fig. 5 for excluded region in the $m_{X^0} - \Gamma(X^0)$ plane.

[5] ADEVA 84 and BEHREND 84C have E_{cm} = 39.8–45.5 GeV. MARK-J searched X^0 in $e^+e^- \to$ hadrons, 2γ, $\mu^+\mu^-$, e^+e^- and CELLO in the same channels plus τ pair. No narrow or broad X^0 is found in the energy range. They also searched for the effect of X^0 with $m_X > E_{cm}$. The second limits are from Bhabha data and for spin-0 singlet. The same limits apply for $\Gamma(X^0 \to e^+e^-)$ = 2 MeV if X^0 is a spin-0 doublet. The second limit of BEHREND 84C was read off from their figure 2. The original papers also list limits in other channels.

Search for X^0 Resonance in e^+e^- Collisions

The limit is for $\Gamma(X^0 \to e^+e^-)\cdot B(X^0 \to f)$, where f is the specified final state. Spin 0 is assumed for X^0.

Axions (A^0) and Other Very Light Bosons, Searches for

See the related review(s):
Axions and Other Similar Particles

A^0 (Axion) MASS LIMITS from Astrophysics and Cosmology

These bounds depend on model-dependent assumptions (i.e. — on a combination of axion parameters).

VALUE (MeV)		DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •					
>0.2		BARROSO	82	ASTR	Standard Axion
>0.25	[1]	RAFFELT	82	ASTR	Standard Axion
>0.2	[2]	DICUS	78C	ASTR	Standard Axion
		MIKAELIAN	78	ASTR	Stellar emission
>0.3	[2]	SATO	78	ASTR	Standard Axion
>0.2		VYSOTSKII	78	ASTR	Standard Axion

[1] Lower bound from 5.5 MeV γ-ray line from the sun.
[2] Lower bound from requiring the red giants' stellar evolution not be disrupted by axion emission.

A^0 (Axion) and Other Light Boson (X^0) Searches in Hadron Decays

Limits are for branching ratios.

[1] ADACHI 23K quoted limit is for $m_{X^0} \simeq 3$ GeV, $c\tau_{X^0} = 1$ cm, and the decay channel $X^0 \to e^+e^-$. See their Fig. 2 for limits with different lifetimes and decay channels, $X^0 \to \mu^+\mu^-$, $\pi^+\pi^-$, K^+K^-.
[2] ADACHI 23K quoted limit is for $m_{X^0} \simeq 2$ GeV, $c\tau_{X^0} = 1$ cm, and the decay channel $X^0 \to e^+e^-$. See their Fig. 2 for limits with different lifetimes and decay channels, $X^0 \to \mu^+\mu^-$, $\pi^+\pi^-$, K^+K^-.
[3] CORTINA-GIL 23B limit extends over 10–170 MeV in mass. Quoted limit is at 155 MeV.

[4] LEES 22B quoted limit is for $m_{A^0} = 3.9$ GeV, assuming the promptly decaying axion. Limits of O(10^{-7}) are obtained for $m_{A^0} = 0.175$–4.78 GeV. See their Figs.3 and 4 for mass and lifetime dependent limits.

[5] ABRATENKO 21 quoted limit is for $m_{X^0} = 150$ MeV and the lifetime $c\tau_{X^0} = 80$ m. See their Fig. 4 for the limits in the range of $m_{X^0} = 10$–210 MeV.

[6] CORTINA-GIL 21 quoted limit is for $m_{X^0} = 370$ MeV. Limits from O(10^{-5}) and O(10^{-6}) are obtained for $m_{X^0} = 10$–370 MeV (see their Fig. 7).

[7] CORTINA-GIL 21A quoted limit is for $m_{X^0} = 160$–250 MeV. Limits between 5×10^{-11} and 2×10^{-10} are obtained in the range of $m_{X^0} = 0$–110 and 154–260 MeV, assuming stable or invisibly decaying X^0. See their Fig. 4 for mass- and lifetime-dependent limits.

[8] CORTINA-GIL 21C quoted limit is for $m_{X^0} = 130$–140 MeV, and limits of 9×10^{-10}–6×10^{-7} are obtained in the mass range of $m_{X^0} = 110$–155 MeV, assuming X^0 escapes detection. See their Fig. 6 for mass- and lifetime-dependent limits.

[9] PARK 21 look for dark photons produced by decays of B^0 through off-shell Higgs-dark Higgs mixing. See their Fig. 5 for limits in the range of $m_{X^0} = 0.01$–2.62 GeV.

[10] AHN 19 is an update of AHN 17 from a new data set. See their Fig. 4 for the limits in the range of $m_{X^0} = 0$–250 MeV.

[11] AAIJ 17AQ limit is for $\tau_{X^0} = 10$ ps. See their Fig. 4 for limits in the range of $m_{X^0} = 250$–4700 MeV and $\tau_{X^0} = 0.1$–1000 ps.

[12] AHN 17 limit as a function of m_{X^0} from 0 to 250 MeV is provided in their Fig. 5.

[13] BATLEY 17 limit is for $m_{X^0} = 216$ MeV and $\tau_{X^0} \leq 10$ ps. See their Fig. 4(c) for limits in the range of $m_{X^0} = 211$–354 MeV and longer lifetimes.

[14] WON 16 look for a vector boson coupled to baryon number. Derived limits on $\alpha' < 10^{-3}$–10^{-2} for $m_{X^0} = 290$–520 MeV at 95% CL. See their Fig. 4 for mass-dependent limits.

[15] AAIJ 15AZ limit is for $\tau_{X^0} = 10$ ps and $m_{X^0} = 214$–4350 MeV. See their Fig. 4 for mass- and lifetime-dependent limits.

[16] ADLARSON 13 limits between 2.0×10^{-5} and 1.5×10^{-6} are obtained for $m_{X^0} = 20$–100 MeV (see their Fig. 8). Angular momentum conservation requires that X^0 has spin ≥ 1.

[17] BABUSCI 13B limit is for $B(\phi \to \eta X^0)\cdot B(X^0 \to e^+e^-)$ and applies to $m_{X^0} = 410$ MeV. It is derived by analyzing $\eta \to \pi^0\pi^0\pi^0$ and $\pi^-\pi^+\pi^0$. Limits between 1×10^{-6} and 2×10^{-8} are obtained for $m_{X^0} \leq 450$ MeV (see their Fig. 6).

[18] ARCHILLI 12 analyzed $\eta \to \pi^+\pi^-\pi^0$ decays. Derived limits on $\alpha'/\alpha < 2\times10^{-5}$ for $m_{X^0} = 50$–420 MeV at 90% CL. See their Fig. 8 for mass-dependent limits.

[19] GNINENKO 12A limit is for $B(\pi^0 \to \gamma X^0)\cdot B(X^0 \to e^+e^-)$ and applies for $m_{X^0} = 90$ MeV and $\tau_{X^0} \simeq 1\times10^{-8}$ sec. Limits between 10^{-8} and 2×10^{-15} are obtained for $m_{X^0} = 3$–120 MeV and $\tau_{X^0} = 1\times10^{-11}$–1 sec. See their Fig. 3 for limits at different masses and lifetimes.

[20] GNINENKO 12B limit is for $B(\eta \to \gamma X^0)\cdot B(X^0 \to e^+e^-)$ and applies for $m_{X^0} = 100$ MeV and $\tau_{X^0} \simeq 6\times10^{-9}$ sec. Limits between 10^{-5} and 3×10^{-14} are obtained for $m_{X^0} \lesssim 550$ MeV and $\tau_{X^0} = 10^{-10}$–10 sec. See their Fig. 5 for limits at different mass and lifetime and for η' decays.

[21] ADLER 04 limit applies for a mass near 180 MeV. For other masses in the range $m_{X^0} = 150$–250 MeV the limit is less restrictive, but still improves ADLER 02C and ATIYA 93B.

[22] ANISIMOVSKY 04 bound is for m_{X^0}=0.

[23] ADLER 02C bound is for m_{X^0} <60 MeV. See Fig. 2 for limits at higher masses.

[24] The quoted limit is for $m_{X^0} = 0$–80 MeV. See their Fig. 5 for the limit at higher mass. The branching fraction limit assumes pure phase space decay distributions.

[25] ALTEGOER 98 looked for X^0 from π^0 decay which penetrate the shielding and convert to π^0 in the external Coulomb field of a nucleus.

[26] KITCHING 97 limit is for $B(K^+ \to \pi^+X^0)\cdot B(X^0 \to \gamma\gamma)$ and applies for $m_{X^0} \simeq 50$ MeV, $\tau_{X^0} < 10^{-10}$ s. Limits are provided for $0<m_{X^0}<100$ MeV, $\tau_{X^0} < 10^{-8}$ s.

[27] ADLER 96 looked for a peak in missing-mass distribution. This work is an update of ATIYA 93. The limit is for massless stable X^0 particles and extends to m_{X^0}=80 MeV at the same level. See paper for dependence on finite lifetime.

[28] AMSLER 94B and AMSLER 96B looked for a peak in missing-mass distribution.

[29] MEIJERDREES 94 limit is based on inclusive photon spectrum and is independent of X^0 decay modes. It applies to $\tau(X^0) > 10^{-23}$ sec.

[30] ATIYA 93B looked for a peak in missing mass distribution. The bound applies for stable X^0 of m_{X^0}=150–250 MeV, and the limit becomes stronger (10^{-8}) for m_{X^0}=180–240 MeV.

[31] NG 93 studied the production of X^0 via $\gamma\gamma \to \pi^0 \to \gamma X^0$ in the early universe at $T\simeq 1$ MeV. The bound on extra neutrinos from nucleosynthesis $\Delta N_\nu < 0.3$ (WALKER 91) is employed. It applies to $m_{X^0} \ll 1$ MeV in order to be relativistic down to nucleosynthesis temperature. See paper for heavier X^0.

[32] ALLIEGRO 92 limit applies for m_{X^0}=150–340 MeV and is the branching ratio times the decay probability. Limit is $< 1.5\times10^{-8}$ at 99%CL.

[33] ATIYA 92 looked for a peak in missing mass distribution. The limit applies to m_{X^0}=0–130 MeV in the narrow resonance limit. See paper for the dependence on lifetime. Covariance requires X^0 to be a vector particle.

[34] BARABASH 92 is a beam dump experiment that searched for a light Higgs. Limits between 1×10^{-12} and 1×10^{-7} are obtained for $3 < m_{X^0} < 40$ MeV.

[35] Limits between 1×10^{-12} and 1 are obtained for $4 < m_{X^0} < 69$ MeV.

[36] Limits between 1×10^{-11} and 5×10^{-3} are obtained for $4 < m_{X^0} < 63$ MeV.

[37] Limits between 1×10^{-14} and 1 are obtained for $3 < m_{X^0} < 82$ MeV.

[38] MEIJERDREES 92 limit applies for $\tau_{X^0} = 10^{-23}$–10^{-11} sec. Limits between 2×10^{-4} and 4×10^{-6} are obtained for $m_{X^0} = 25$–120 MeV. Angular momentum conservation requires that X^0 has spin ≥ 1.

[39] ATIYA 90B limit is for $B(K^+ \to \pi^+X^0)\cdot B(X^0 \to \gamma\gamma)$ and applies for $m_{X^0} = 50$ MeV, $\tau_{X^0} < 10^{-10}$ s. Limits are also provided for $0 < m_{X^0} < 100$ MeV, $\tau_{X^0} < 10^{-8}$ s.

[40] KORENCHENKO 87 limit assumes $m_{A^0} = 1.7$ MeV, $\tau_{A^0} \lesssim 10^{-12}$ s, and $B(A^0 \to e^+e^-) = 1$.

[41] EICHLER 86 looked for $\pi^+ \to e^+\nu A^0$ followed by $A^0 \to e^+e^-$. Limits on the branching fraction depend on the mass and and lifetime of A^0. The quoted limits are valid when $\tau(A^0) \gtrsim 3.\times10^{-10}$s if the decays are kinematically allowed.

[42] YAMAZAKI 84 looked for a discrete line in $K^+ \to \pi^+$X. Sensitive to wide mass range (5–300 MeV), independent of whether X decays promptly or not.

[43] ASANO 82 at KEK set limits for $B(K^+ \to \pi^+X^0)$ for m_{X^0} <100 MeV as BR $< 4.\times10^{-8}$ for $\tau(X^0 \to n\gamma\text{'s}) > 1.\times10^{-9}$ s, BR $< 1.4\times10^{-6}$ for $\tau < 1.\times10^{-9}$s.

[44] ASANO 81B is KEK experiment. Set $B(K^+ \to \pi^+X^0) < 3.8\times10^{-8}$ at CL = 90%.

[45] ZHITNITSKII 79 argue that a heavy axion predicted by YANG 78 (3 <m <40 MeV) contradicts experimental muon anomalous magnetic moments.

A^0 (Axion) Searches in Quarkonium Decays

Decay or transition of quarkonium. Limits are for branching ratio.

[1] ABLIKIM 23E obtained limits in the range of 8.3×10^{-8}–1.8×10^{-6} for 0.165 GeV $\leq m_{A^0} \leq$ 2.84 GeV. See their Fig. 5 for mass-dependent limits.

[2] JIA 22 limits between 3.1×10^{-7}–1.6×10^{-5} were obtained for 0.22 GeV $< m_{A^0} <$ 9.2 GeV. See their Fig. 4 for mass-dependent limits.

[3] ABLIKIM 16E limits between 2.8–495.3×10^{-8} were obtained for 0.212 GeV $< m_{A^0} <$ 3.0 GeV. See their Fig. 5 for mass-dependent limits.

[4] ABLIKIM 12 derived limits between 4×10^{-7}–2.1×10^{-5} for 0.212 GeV $< m_{A^0} <$ 3.0 GeV. See their Fig. 2(c) for mass-dependent limits.

[5] ANTREASYAN 90C assume that A^0 does not decay in the detector.

[6] The first DRUZHININ 87 limit is valid when $\tau_{A^0}/m_{A^0} < 3\times10^{-13}$ s/MeV and $m_{A^0} <$ 20 MeV.

[7] The second DRUZHININ 87 limit is valid when $\tau_{A^0}/m_{A^0} < 5\times10^{-13}$ s/MeV and $m_{A^0} <$ 20 MeV.

[8] The third DRUZHININ 87 limit is valid when $\tau_{A^0}/m_{A^0} > 7\times10^{-12}$ s/MeV and $m_{A^0} <$ 200 MeV.

[9] EDWARDS 82 looked for $J/\psi \to \gamma A^0$ decays by looking for events with a single γ [of energy $\sim$ 1/2 the $J/\psi(1S)$ mass], plus nothing else in the detector. The limit is inconsistent with the axion interpretation of the FAISSNER 81B result.

A^0 (Axion) Searches in Positronium Decays

Decay or transition of positronium. Limits are for branching ratio.

		[7] AMALDI	85	CNTR	Ortho-positronium
		[8] CARBONI	83	CNTR	Ortho-positronium

[1] BADERTSCHER 02 looked for a three-body decay of ortho-positronium into a photon and two penetrating (neutral or milli-charged) particles.

[2] The ASAI 94 limit is based on inclusive photon spectrum and is independent of A^0 decay modes.

[3] The AKOPYAN 91 limit applies for a short-lived A^0 with $\tau_{A^0} < 10^{-13}$ m_{A^0} [keV] s.

[4] ASAI 91 limit translates to $g^2_{A^0e^+e^-}/4\pi < 1.1\times10^{-11}$ (90% CL) for $m_{A^0} <$ 800 keV.

[5] The TSUCHIAKI 90 limit is based on inclusive photon spectrum and is independent of A^0 decay modes.

[6] ORITO 89 limit translates to $g^2_{A^0ee}/4\pi < 6.2\times10^{-10}$. Somewhat more sensitive limits are obtained for larger m_{A^0}: $B < 7.6\times10^{-6}$ at 100 keV.

[7] AMALDI 85 set limits $B(A^0\gamma)$ / $B(\gamma\gamma\gamma) < (1$–$5)\times10^{-6}$ for m_{A^0} = 900–100 keV which are about 1/10 of the CARBONI 83 limits.

[8] CARBONI 83 looked for orthopositronium $\to A^0\gamma$. Set limit for A^0 electron coupling squared, $g(eeA^0)^2/(4\pi) < 6.\times10^{-10}$–$7.\times10^{-9}$ for m_{A^0} from 150–900 keV (CL = 99.7%). This is about 1/10 of the bound from g–2 experiments.

A^0 (Axion) Search in Photoproduction

VALUE	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
	[1] ADHIKARI	22C	GLUX	m_{A^0} = 180–480, 600–720 MeV
	[2] BASSOMPIE...	95		m_{A^0} = 1.8 ± 0.2 MeV

[1] ADHIKARI 22C search for $A^0 \to \gamma\gamma$ and $A^0 \to \pi^+\pi^-\pi^0$ decays, and set limits of $f_{A^0} \lesssim$ 0.5–14 GeV at 90% CL. See their Fig. 4 for mass-dependent limits.

[2] BASSOMPIERRE 95 is an extension of BASSOMPIERRE 93. They looked for a peak in the invariant mass of e^+e^- pairs in the region $m_{e^+e^-}$ = 1.8 ± 0.2 MeV. They obtained bounds on the production rate A^0 for $\tau(A^0) = 10^{-18}$–10^{-9} sec. They also found an excess of events in the range $m_{e^+e^-}$ = 2.1–3.5 MeV.

A^0 (Axion) Production in Hadron Collisions

Limits are for $\sigma(A^0)$ / $\sigma(\pi^0)$.

[1] ACCIARRI 23 search for axions in the NuMI neutrino beam target, which are produced through mixings with mesons due to the coupling with gluons, and exclude f_{A^0} around tens of TeV for m_{A^0} = 0.2–0.9 GeV. They assume a slightly suppressed axion coupling to muons. See their Fig. 4 for the limits.

[2] BERTUZZO 23 employs an analysis analogous to ACCIARRI 23. They search for leptophilic axions primarily produced via $\tau \to \mu A^0$ and $\tau \to eA^0$, and exclude f_{A^0} around 1×10^6–6×10^7 GeV for m_{A^0} = 0.2–1.7 GeV. See their Fig. 2 for the limits.

[3] AAD 22J set upper limits for the cross sections of $H \to A^0A^0 \to 4\mu$ and $H \to ZA^0 \to 2\ell 2\mu$. See their Figs. 14 and 17 for the respective mass-dependent limits.

[4] TUMASYAN 22AH set the limits of $O(10^{-6})$ with respect to the product of the branching fractions of $H \to A^0A^0$ and $A^0 \to e^+e^-$, $\mu^+\mu^-$. They also derive limits on the effective axion couplings contributing to $H \to A^0A^0$ and $H \to ZA^0$. See their Figs. 5 and 7 for the limits.

[5] TUMASYAN 22R is analogous to GAVELA 20, and set a limit on the products of the axion couplings to gluons and Z bosons as $G_{AZZ}\, G_{Agg} < 6.64 \times 10^{-7}$ GeV^{-2} at 95% CL for f_{A^0} = 3 TeV and $m_{A^0} < 100$ GeV. Here we use $c_{\widetilde{G}} = G_{Agg}\, f_{A^0}/4$ and $c_{\widetilde{Z}} = G_{AZZ}\, f_{A^0}/4$ to translate their limits. They also set a limit on the product of the axion couplings to gluons and ZH. See their Fig. 9 for the f_{A^0}-dependent limits.

[6] AAD 21F look for axion production with an energetic jet and large missing p_T, and set a limit on the axion coupling to gluons, $c_{\widetilde{G}}/f_{A^0} < 8 \times 10^{-6}$ GeV^{-1} at 95 % CL for m_{A^0} = 1 MeV. Using $c_{\widetilde{G}} = \alpha_s/8\pi$, we interpret the limit as $f_{A^0} > 0.4$ TeV for $\alpha_s \simeq 0.08$.

[7] AAD 21K look for axion production with an energetic photon and large missing p_T, and set a limit on the axion coupling to a Z boson and photon, $G_{AZ\gamma} < 5.1 \times 10^{-4}$ GeV^{-1} at 95 % CL for m_{A^0} = 1 MeV and assuming $G_{A\gamma\gamma} = 0$.

[8] AAD 21N look for axion production using the measurement of light-by-light scattering based on Pb+Pb collision data. They set the limit on the axion-photon coupling, $G_{A\gamma\gamma} < 5.3 \times 10^{-5}$–$3.4 \times 10^{-4}$ GeV^{-1} at 95 % CL for m_{A^0} = 6–100 GeV. Here we use $\Lambda_a = G_{A\gamma\gamma}{}^{-1}$ to translate their limits. See their Fig. 9 for mass-dependent limits.

[9] CARRA 21 is analogous to GAVELA 20, and they use the differential cross sections for WW and $Z\gamma$ production measured with the ATLAS detector to set limits on the product of the axion couplings to gauge bosons as $G_{AWW}\, G_{Agg} < 6.2 \times 10^{-7}$ GeV^{-2} and $G_{AZ\gamma}\, G_{Agg} < 3.7 \times 10^{-7}$ GeV^{-2} at 95 % CL for $m_{A^0} \lesssim$ 100 GeV.

[10] AAIJ 20AL look for a light new boson decaying into a pair of muons using the LHCb data with an integrated luminosity of 5.1 fb^{-1}, and set limits on the cross section over a range of m_{X^0} = 0.22–3 and 20–60 GeV. See Figs. 8 and 9 for mass-dependent limits.

[11] GAVELA 20 focus on the axion production as an s-channel off shell mediator, and use the Run 2 CMS public data to set limits on the product of the axion couplings to gluons and photons as well as Z bosons as $G_{A\gamma\gamma}\, G_{Agg} < 2.8 \times 10^{-7}$ GeV^{-2} and $G_{AZZ}\, G_{Agg} < 9.8 \times 10^{-7}$ GeV^{-2} for $m_{A^0} \lesssim$ 200 GeV. See their Fig.3 for the limits.

[12] SIRUNYAN 19BQ look for the pair production of a new light boson decaying into a pair of muons, and set limits on the product of the production cross section times branching fraction to dimuons squared times acceptance over a range of m_{X^0} = 0.25–8.5 GeV. See the right panel of their Fig. 1 for mass-dependent limits.

[13] JAIN 07 claims evidence for $A^0 \to e^+e^-$ produced in ^{207}Pb collision on nuclear emulsion (Ag/Br) for $m(A^0) = 7 \pm 1$ or 19 ± 1 MeV and $\tau(A^0) \leq 10^{-13}$ s.

[14] AHMAD 97 reports a result of APEX Collaboration which studied positron production in ^{238}U+^{232}Ta and ^{238}U+^{181}Ta collisions, without requiring a coincident electron. No narrow lines were found for $250 < E_{e^+} < 750$ keV.

[15] LEINBERGER 97 (ORANGE Collaboration) at GSI looked for a narrow sum-energy e^+e^--line at $\sim$ 635 keV in ^{238}U+^{181}Ta collision. Limits on the production probability for a narrow sum-energy e^+e^- line are set. See their Table 2.

[16] GANZ 96 (EPos II Collaboration) has placed upper bounds on the production cross section of e^+e^- pairs from ^{238}U+^{181}Ta and ^{238}U+^{232}Th collisions at GSI. See Table 2 for limits both for back-to-back and isotropic configurations of e^+e^- pairs. These limits rule out the existence of peaks in the e^+e^- sum-energy distribution, reported by an earlier version of this experiment.

[17] KAMEL 96 looked for e^+e^- pairs from the collision of ^{32}S (200 GeV/nucleon) and emulsion. No evidence of mass peaks is found in the region of sensitivity $m_{ee} > 2$ MeV.

[18] BLUEMLEIN 92 is a proton beam dump experiment at Serpukhov with a secondary target to induce Bethe-Heitler production of e^+e^- or $\mu^+\mu^-$ from the produce A^0. See Fig. 5 for the excluded region in m_{A^0}-x plane. For the standard axion, $0.3 < x < 25$ is excluded at 95% CL. If combined with BLUEMLEIN 91, $0.008 < x < 32$ is excluded.

[19] MEIJERDREES 92 give $\Gamma(\pi^-p \to nA^0)\cdot B(A^0 \to e^+e^-)/\Gamma(\pi^-p \to \text{all}) < 10^{-5}$ (90% CL) for m_{A^0} = 100 MeV, $\tau_{A^0} = 10^{-11}$–10^{-23} sec. Limits ranging from 2.5×10^{-3} to 10^{-7} are given for m_{A^0} = 25–136 MeV.

[20] BLUEMLEIN 91 is a proton beam dump experiment at Serpukhov. No candidate event for $A^0 \to e^+e^-$, 2γ are found. Fig. 6 gives the excluded region in m_{A^0}-x plane ($x = \tan\beta = v_2/v_1$). Standard axion is excluded for $0.2 < m_{A^0} < 3.2$ MeV for most $x > 1$, 0.2–11 MeV for most $x < 1$.

[21] FAISSNER 89 searched for $A^0 \to e^+e^-$ in a proton beam dump experiment at SIN. No excess of events was observed over the background. A standard axion with mass $2m_e$–20 MeV is excluded. Lower limit on f_{A^0} of $\simeq 10^4$ GeV is given for $m_{A^0} = 2m_e$–20 MeV.

[22] DEBOER 88 reanalyze EL-NADI 88 data and claim evidence for three distinct states with mass $\sim$ 1.1, $\sim$ 2.1, and $\sim$ 9 MeV, lifetimes 10^{-16}–10^{-15} s decaying to e^+e^- and note the similarity of the data with those of a cosmic-ray experiment by Bristol group (B.M. Anand, Proc. of the Royal Society of London, Section A **A22** 183 (1953)). For a criticism see PERKINS 89, who suggests that the events are compatible with π^0 Dalitz decay. DEBOER 89B is a reply which contests the criticism.

[23] EL-NADI 88 claim the existence of a neutral particle decaying into e^+e^- with mass 1.60 ± 0.59 MeV, lifetime (0.15 ± 0.01) $\times 10^{-14}$ s, which is produced in heavy ion interactions with emulsion nuclei at $\sim$ 4 GeV/c/nucleon.

[24] FAISSNER 88 is a proton beam dump experiment at SIN. They found no candidate event for $A^0 \to \gamma\gamma$. A standard axion decaying to 2γ is excluded except for a region $x \simeq 1$. Lower limit on f_{A^0} of 10^2–10^3 GeV is given for m_{A^0} = 0.1–1 MeV.

[25] BADIER 86 did not find long-lived A^0 in 300 GeV π^- Beam Dump Experiment that decays into e^+e^- in the mass range m_{A^0} = (20–200) MeV, which excludes the A^0 decay constant $f(A^0)$ in the interval (60–600) GeV. See their figure 6 for excluded region on $f(A^0)$-m_{A^0} plane.

[26] BERGSMA 85 look for $A^0 \to 2\gamma$, e^+e^-, $\mu^+\mu^-$. First limit above is for m_{A^0} = 1 MeV; second is for 200 MeV. See their figure 4 for excluded region on f_{A^0}–m_{A^0} plane,

Gauge & Higgs Boson Particle Listings

Axions (A^0) and Other Very Light Bosons

where f_{A^0} is A^0 decay constant. For Peccei-Quinn PECCEI 77 A^0, m_{A^0} <180 keV and τ >0.037 s. (CL = 90%). For the axion of FAISSNER 81B at 250 keV, BERGSMA 85 expect 15 events but observe zero.

[27] FAISSNER 83 observed 19 1-γ and 12 2-γ events where a background of 4.8 and 2.3 respectively is expected. A small-angle peak is observed even if iron wall is set in front of the decay region.

[28] FAISSNER 83B extrapolate SIN γ signal to LAMPF ν experimental condition. Resulting 370 γ's are not at variance with LAMPF upper limit of 450 γ's. Derived from LAMPF limit that $[d\sigma(A^0)/d\omega$ at $90^\circ] m_{A^0}/\tau_{A^0} < 14\times10^{-35}$ cm^2 sr^{-1} MeV ms^{-1}. See comment on FRANK 83B.

[29] FRANK 83B stress the importance of LAMPF data bins with negative net signal. By statistical analysis say that LAMPF and SIN-A0 are at variance when extrapolation by phase-space model is done. They find LAMPF upper limit is 248 not 450 γ's. See comment on FAISSNER 83B.

[30] HOFFMAN 83 set CL = 90% limit $d\sigma/dt\ \mathrm{B}(e^+e^-) < 3.5\times10^{-32}$ cm^2/GeV^2 for 140 $< m_{A^0} <$160 MeV. Limit assumes $\tau(A^0) < 10^{-9}$ s.

[31] FETSCHER 82 reanalyzes SIN beam-dump data of FAISSNER 81. Claims no evidence for axion since 2-γ peak rate remarkably decreases if iron wall is set in front of the decay region.

[32] FAISSNER 81 see excess μe events. Suggest axion interactions.

[33] FAISSNER 81B is SIN 590 MeV proton beam dump. Observed 14.5 $\pm$ 5.0 events of 2γ decay of long-lived neutral penetrating particle with $m_{2\gamma} \lesssim 1$ MeV. Axion interpretation with η-A^0 mixing gives $m_{A^0} = 250 \pm 25$ keV, $\tau_{(2\gamma)} = (7.3 \pm 3.7)\times10^{-3}$ s from above rate. See critical remarks below in comments of FETSCHER 82, FAISSNER 83, FAISSNER 83B, FRANK 83B, and BERGSMA 85. Also see in the next subsection ALEKSEEV 82B, CAVAIGNAC 83, and ANANEV 85.

[34] KIM 81 analyzed 8 candidates for $A^0 \to 2\gamma$ obtained by Aachen-Padova experiment at CERN with 26 GeV protons on Be. Estimated axion mass is about 300 keV and lifetime is $(0.86\sim5.6)\times10^{-3}$ s depending on models. Faissner (private communication), says axion production underestimated and mass overestimated. Correct value around 200 keV.

[35] FAISSNER 80 is SIN beam dump experiment with 590 MeV protons looking for $A^0 \to e^+e^-$ decay. Assuming $A^0/\pi^0 = 5.5\times10^{-7}$, obtained decay rate limit 20/(A^0 mass) MeV/s (CL = 90%), which is about 10^{-7} below theory and interpreted as upper limit to $m_{A^0} < 2m_{e^-}$.

[36] JACQUES 80 is a BNL beam dump experiment. First limit above comes from nonobservation of excess neutral-current-type events $[\sigma(\text{production})\sigma(\text{interaction}) < 7.\times10^{-68}$ cm^4, CL = 90%]. Second limit is from nonobservation of axion decays into 2γ's or e^+e^-, and for axion mass a few MeV.

[37] SOUKAS 80 at BNL observed no excess of neutral-current-type events in beam dump.

[38] BECHIS 79 looked for the axion production in low energy electron Bremsstrahlung and the subsequent decay into either 2γ or e^+e^-. No signal found. CL = 90% limits for model parameter(s) are given.

[39] COTEUS 79 is a beam dump experiment at BNL.

[40] DISHAW 79 is a calorimetric experiment and looks for low energy tail of energy distributions due to energy lost to weakly interacting particles.

[41] BELLOTTI 78 first value comes from search for $A^0 \to e^+e^-$. Second value comes from search for $A^0 \to 2\gamma$, assuming mass $< 2m_{e^-}$. For any mass satisfying this, limit is above value$\times$(mass^{-4}). Third value uses data of PL 60B 401 and quotes $\sigma(\text{production})\sigma(\text{interaction}) < 10^{-67}$ cm^4.

[42] BOSETTI 78B quotes $\sigma(\text{production})\sigma(\text{interaction}) < 2.\times10^{-67}$ cm^4.

[43] DONNELLY 78 examines data from reactor neutrino experiments of REINES 76 and GURR 74 as well as SLAC beam dump experiment. Evidence is negative.

[44] MICELMACHER 78 finds no evidence of axion existence in reactor experiments of REINES 76 and GURR 74. (See reference under DONNELLY 78 below).

[45] VYSOTSKII 78 derived lower limit for the axion mass 25 keV from luminosity of the sun and 200 keV from red supergiants.

A^0 (Axion) Searches in Reactor Experiments

VALUE	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
	[1] CHANG	07		Primakoff or Compton
	[2] ALTMANN	95	CNTR	Reactor; $A^0 \to e^+e^-$
	[3] KETOV	86	SPEC	Reactor; $A^0 \to \gamma\gamma$
	[4] KOCH	86	SPEC	Reactor; $A^0 \to \gamma\gamma$
	[5] DATAR	82	CNTR	Light water reactor
	[6] VUILLEUMIER	81	CNTR	Reactor, $A^0 \to 2\gamma$

[1] CHANG 07 looked for monochromatic photons from Primakoff or Compton conversion of axions from the Kuo-Sheng reactor due to axion coupling to photon or electron, respectively. The search places model-independent limits on the products $G_{A\gamma\gamma}G_{ANN}$ and $G_{Aee}G_{ANN}$ for $m(A^0)$ less than the MeV range.

[2] ALTMANN 95 looked for A^0 decaying into e^+e^- from the Bugey5 nuclear reactor. They obtain an upper limit on the A^0 production rate of $\omega(A^0)/\omega(\gamma)\times\mathrm{B}(A^0 \to e^+e^-) < 10^{-16}$ for $m_{A^0} = 1.5$ MeV at 90% CL. The limit is weaker for heavier A^0. In the case of a standard axion, this limit excludes a mass in the range $2m_e < m_{A^0} < 4.8$ MeV at 90% CL. See Fig. 5 of their paper for exclusion limits of axion-like resonances Z^0 in the (m_{X^0},f_{X^0}) plane.

[3] KETOV 86 searched for A^0 at the Rovno nuclear power plant. They found an upper limit on the A^0 production probability of 0.8 $[100\ \text{keV}/m_{A^0}]^6 \times10^{-6}$ per fission. In the standard axion model, this corresponds to $m_{A^0} >$150 keV. Not valid for $m_{A^0} \gtrsim 1$ MeV.

[4] KOCH 86 searched for $A^0 \to \gamma\gamma$ at nuclear power reactor Biblis A. They found an upper limit on the A^0 production rate of $\omega(A^0)/\omega(\gamma(M1)) < 1.5\times10^{-10}$ (CL=95%). Standard axion with $m_{A^0} = 250$ keV gives 10^{-5} for the ratio. Not valid for $m_{A^0} >$1022 keV.

[5] DATAR 82 looked for $A^0 \to 2\gamma$ in neutron capture ($np \to dA^0$) at Tarapur 500 MW reactor. Sensitive to sum of $I = 0$ and $I = 1$ amplitudes. With ZEHNDER 81 $[(I = 0) - (I = 1)]$ result, assert nonexistence of standard A^0.

[6] VUILLEUMIER 81 is at Grenoble reactor. Set limit $m_{A^0} <$280 keV.

A^0 (Axion) and Other Light Boson (X^0) Searches in Nuclear Transitions

Limits are for branching ratio.

		[23] CALAPRICE	79		Carbon

[1] DERBIN 23 use a thallium garnet bolometric detector to search for the 8.4 keV solar axion line emitted from the M1 nuclear transition of ^{169}Tm. Their limits are equivalent to an upper bound on the KSVZ and DFSZ axion masses of 141 eV and 244 eV, respectively.

[2] DERBIN 02 looked for the axion emission in an M1 transition in ^{125m}Te decay. They looked for a possible presence of a shifted energy spectrum in gamma rays due to the undetected axion.

[3] DEBOER 97C reanalyzed the existent data on Nuclear M1 transitions and find that a 9 MeV boson decaying into e^+e^- would explain the excess of events with large opening angles. See also DEBOER 01 for follow-up experiments.

[4] TSUNODA 95 looked for axion emission when ^{252}Cf undergoes a spontaneous fission, with the axion decaying into e^+e^-. The bound is for m_{A^0}=40 MeV. It improves to 2.5×10^{-5} for m_{A^0}=200 MeV.

[5] MINOWA 93 studied chain process, ^{139}Ce $\to$ ^{139}La* by electron capture and M1 transition of ^{139}La* to the ground state. It does not assume decay modes of A^0. The bound applies for $m_{A^0} < 166$ keV.

[6] HICKS 92 bound is applicable for $\tau_{X^0} < 4\times10^{-11}$ sec.

[7] The ASANUMA 90 limit is for the branching fraction of X^0 emission per ^{241}Am α decay and valid for $\tau_{X^0} < 3\times10^{-11}$ s.

[8] The DEBOER 90 limit is for the branching ratio ^{8}Be* (18.15 MeV, 1^+) $\to$ ^{8}BeA^0, $A^0 \to e^+e^-$ for the mass range m_{A^0} = 4–15 MeV.

[9] The BINI 89 limit is for the branching fraction of ^{16}O*(6.05 MeV, 0^+) $\to$ ^{16}OX^0, $X^0 \to e^+e^-$ for m_X = 1.5–3.1 MeV. $\tau_{X^0} \lesssim 10^{-11}$ s is assumed. The spin-parity of X is restricted to 0^+ or 1^-.

[10] AVIGNONE 88 looked for the 1115 keV transition C* $\to$ CuA^0, either from $A^0 \to 2\gamma$ in-flight decay or from the secondary A^0 interactions by Compton and by Primakoff processes. Limits for axion parameters are obtained for $m_{A^0} < 1.1$ MeV.

[11] DATAR 88 rule out light pseudoscalar particle emission through its decay $A^0 \to e^+e^-$ in the mass range 1.02–2.5 MeV and lifetime range 10^{-13}–10^{-8} s. The above limit is for $\tau = 5\times10^{-13}$ s and m = 1.7 MeV; see the paper for the τ-m dependence of the limit.

[12] The limit is for the branching fraction of ^{16}O*(6.05 MeV, 0^+) $\to$ ^{16}OX^0, $X^0 \to e^+e^-$ against internal pair conversion for m_{X^0} = 1.7 MeV and $\tau_{X^0} < 10^{-11}$ s. Similar limits are obtained for m_{X^0} = 1.3–3.2 MeV. The spin parity of X^0 must be either 0^+ or 1^-. The limit at 1.7 MeV is translated into a limit for the X^0-nucleon coupling constant: $g^2_{X^0NN}/4\pi < 2.3\times10^{-9}$.

[13] The DOEHNER 88 limit is for m_{A^0} = 1.7 MeV, $\tau(A^0) < 10^{-10}$ s. Limits less than 10^{-4} are obtained for m_{A^0} = 1.2–2.2 MeV.

[14] SAVAGE 88 looked for A^0 that decays into e^+e^- in the decay of the 9.17 MeV $J^P = 2^+$ state in ^{14}N, 17.64 MeV state $J^P = 1^+$ in ^{8}Be, and the 18.15 MeV state $J^P = 1^+$ in ^{8}Be. This experiment constrains the isovector coupling of A^0 to hadrons, if m_{A^0}

= (1.1 → 2.2) MeV and the isoscalar coupling of A^0 to hadrons, if m_{A^0} = (1.1 → 2.6) MeV. Both limits are valid only if $\tau(A^0) \lesssim 1\times10^{-11}$ s.

[15] Limits are for $\Gamma(A^0(1.8\text{ MeV}))/\Gamma(\pi\text{M1})$; i.e., for 1.8 MeV axion emission normalized to the rate for internal emission of e^+e^- pairs. Valid for $\tau_{A^0} < 2\times10^{-11}$s. ^{6}Li isovector decay data strongly disfavor PECCEI 86 model I, whereas the ^{10}B and ^{14}N isoscalar decay data strongly reject PECCEI 86 model II and III.

[16] SAVAGE 86B looked for A^0 that decays into e^+e^- in the decay of the 9.17 MeV $J^P = 2^+$ state in ^{14}N. Limit on the branching fraction is valid if $\tau_{A^0} \lesssim 1.\times10^{-11}$s for m_{A^0} = (1.1–1.7) MeV. This experiment constrains the iso-vector coupling of A^0 to hadrons.

[17] ANANEV 85 with IBR-2 pulsed reactor exclude standard A^0 at CL = 95% masses below 470 keV (Li* decay) and below $2m_e$ for deuteron* decay.

[18] CAVAIGNAC 83 at Bugey reactor exclude axion at any $m_{^{97}\text{Nb*decay}}$ and axion with m_{A^0} between 275 and 288 keV (deuteron* decay).

[19] ALEKSEEV 82 with IBR-2 pulsed reactor exclude standard A^0 at CL = 95% mass-ranges m_{A^0} <400 keV (Li* decay) and 330 keV <m_{A^0} <2.2 MeV. (deuteron* decay).

[20] LEHMANN 82 obtained $A^0 \to 2\gamma$ rate $< 6.2\times10^{-5}$/s (CL = 95%) excluding m_{A^0} between 100 and 1000 keV.

[21] ZEHNDER 82 used Gosgen 2.8GW light-water reactor to check A^0 production. No 2γ peak in Li*, Nb* decay (both single p transition) nor in n capture (combined with previous Ba* negative result) rules out standard A^0. Set limit m_{A^0} <60 keV for any A^0.

[22] ZEHNDER 81 looked for Ba* → A^0Ba transition with $A^0 \to 2\gamma$. Obtained 2γ coincidence rate $< 2.2\times10^{-5}$/s (CL = 95%) excluding m_{A^0} >160 keV (or 200 keV depending on Higgs mixing). However, see BARROSO 81.

[23] CALAPRICE 79 saw no axion emission from excited states of carbon. Sensitive to axion mass between 1 and 15 MeV.

A^0 (Axion) Limits from Its Electron Coupling

Limits are for $\tau(A^0 \to e^+e^-)$.

[1] ANDREEV 21 look for invisible decays of axions coupled to electrons, and set limits on $g_{Aee} < 4.6\times10^{-6}$–$3.1\times10^{-3}$ for $m_{A^0} = 10^{-3}$–1 GeV. This limits the axion contribution to the electron g–2 to an order of magnitude less than the current experimental uncertainty. See their Figs. 3 and 4 for mass-dependent limits.

[2] ANDREEV 21B set limits on g_{Aee} in the range of 6.3×10^{-6}–1.6×10^{-3} for m_{A^0} = 2–17 MeV at 90% CL. This excludes $6.6\times10^{-5} < g_{Aee} < 1\times10^{-4}$ at m_{A^0} = 16.7 MeV corresponding to the ATOMKI anomaly. See their Fig. 2 for mass-dependent limits.

[3] The listed BROSS 91 limit is for m_{A^0} = 1.14 MeV. B($A^0 \to e^+e^-$) = 1 assumed. Excluded domain in the τ_{A^0}–m_{A^0} plane extends up to $m_{A^0} \approx 7$ MeV (see Fig. 5). Combining with electron g–2 constraint, axions coupling only to e^+e^- ruled out for $m_{A^0} < 4.8$ MeV (90% CL).

[4] GUO 90 use the same apparatus as BROWN 86 and improve the previous limit in the shorter lifetime region. Combined with g–2 constraint, axions coupling only to e^+e^- are ruled out for $m_{A^0} < 2.7$ MeV (90% CL).

[5] BJORKEN 88 reports limits on axion parameters (f_A, m_A, τ_A) for $m_{A^0} < 200$ MeV from electron beam-dump experiment with production via Primakoff photoproduction, bremsstrahlung from electrons, and resonant annihilation of positrons on atomic electrons.

[6] BLINOV 88 assume zero spin, m = 1.8 MeV and lifetime $< 5\times10^{-12}$ s and find $\Gamma(A^0 \to \gamma\gamma)\text{B}(A^0 \to e^+e^-) < 2$ eV (CL=90%).

[7] Assumes $A^0\gamma\gamma$ coupling is small and hence Primakoff production is small. Their figure 2 shows limits on axions for $m_{A^0} < 15$ MeV.

[8] Uses electrons in hadronic showers from an incident 800 GeV proton beam. Limits for $m_{A^0} < 15$ MeV are shown in their figure 3.

[9] m_{A^0} = 1.8 MeV assumed. The excluded domain in the τ_{A^0}–m_{A^0} plane extends up to $m_{A^0} \approx 14$ MeV, see their figure 4.

[10] The limits are obtained from their figure 3. Also given is the limit on the $A^0\gamma\gamma$–$A^0e^+e^-$ coupling plane by assuming Primakoff production.

Search for A^0 (Axion) Resonance in Bhabha Scattering

The limit is for $\Gamma(A^0)[\text{B}(A^0 \to e^+e^-)]^2$.

<2500	90	MILLS	87	CNTR	m_{A^0} = 1.8 MeV
		[10] VONWIMMER..	87	CNTR	

[1] HALLIN 92 quote limits on lifetime, 8×10^{-14} – 5×10^{-13} sec depending on mass, assuming B($A^0 \to e^+e^-$) = 100%. They say that TSERTOS 91 overstated their sensitivity by a factor of 3.

[2] HENDERSON 92C exclude axion with lifetime τ_{A^0}=1.4×10^{-12} – 4.0×10^{-10} s, assuming B($A^0 \to e^+e^-$)=100%. HENDERSON 92C also exclude a vector boson with τ=1.4×10^{-12} – 6.0×10^{-10} s.

[3] WU 92 quote limits on lifetime $> 3.3\times10^{-13}$s assuming B($A^0 \to e^+e^-$)=100%. They say that TSERTOS 89 overestimate the limit by a factor of $\pi/2$. WU 92 also quote a bound for vector boson, $\tau > 8.2\times10^{-13}$s.

[4] WIDMANN 91 bound applies exclusively to the case B($A^0 \to e^+e^-$)=1, since the detection efficiency varies substantially as $\Gamma(A^0)_{\text{total}}$ changes. See their Fig. 6.

[5] JUDGE 90 excludes an elastic pseudoscalar e^+e^- resonance for 4.5×10^{-13}s < $\tau(A^0)$ < 7.5×10^{-12} s (95% CL) at m_{A^0} = 1.832 MeV. Comparable limits can be set for m_{A^0} = 1.776–1.856 MeV.

[6] See also TSERTOS 88B in references.

[7] The upper limit listed in TSERTOS 88 is too large by a factor of 4. See TSERTOS 88B, footnote 3.

[8] VANKLINKEN 88 looked for relatively long-lived resonance ($\tau = 10^{-10}$–10^{-12} s). The sensitivity is not sufficient to exclude such a narrow resonance.

[9] MAIER 87 obtained limits $R\Gamma \lesssim 60$ eV (100 eV) at $m_{A^0} \simeq 1.64$ MeV (1.83 MeV) for energy resolution $\Delta E_{\text{cm}} \simeq 3$ keV, where R is the resonance cross section normalized to that of Bhabha scattering, and $\Gamma = \Gamma^2_{ee}/\Gamma_{\text{total}}$. For a discussion implying that $\Delta E_{\text{cm}} \simeq 10$ keV, see TSERTOS 89.

[10] VONWIMMERSPERG 87 measured Bhabha scattering for E_{cm} = 1.37–1.86 MeV and found a possible peak at 1.73 with $\int\sigma dE_{\text{cm}} = 14.5 \pm 6.8$ keV·b. For a comment and a reply, see VANKLINKEN 88B and VONWIMMERSPERG 88. Also see CONNELL 88.

[1] ADACHI 23A set limits in the range of 1.1×10^{-3}–9.7×10^{-3} for $0 < m_{X^0} < 1.6$ GeV on B($\tau^- \to e^- X^0$)/B($\tau^- \to e^- \overline{\nu}_e \nu_\tau$). See their Fig. 2 for mass-dependent limits.
[2] ADACHI 23A set limits in the range of 7×10^{-4}–1.22×10^{-2} for $0 < m_{X^0} < 1.6$ GeV on B($\tau^- \to \mu^- X^0$)/B($\tau^- \to \mu^- \overline{\nu}_\mu \nu_\tau$). See their Fig. 2 for mass-dependent limits.
[3] FIORILLO 23 used data from Kamiokande-II and IMB on the neutrino flux from SN1987A to constrain the universal neutrino Majoron Yukawa coupling, g. They set an upper limit of $g\, m_{X^0} \lesssim 10^{-9}$ MeV for Majoron masses 100 eV $\lesssim m_{X^0} \lesssim$ 100 MeV, using neutrino coalescence as production of Majorons which then decay back to neutrinos. See their Fig. 1 for the mass-dependent limits.
[4] SANDNER 23 study Majoron production via neutrino inverse decay and use Planck data to constrain the neutrino Majoron Yukawa coupling to $g \lesssim 2\times10^{-13}$–$1\times10^{-12}$ for Majoron masses m_{X^0} = 1–10 eV. See their Fig. 1 for mass-dependent limits.
[5] COLOMA 22A used the spectral data of Borexino Phase II to constrain the neutrino non-standard interaction with electrons mediated by a scalar or a pseudoscalar. Limits on the universal coupling to neutrinos and electrons between 2×10^{-6} and 10^{-4} are obtained for $m_{X^0} \lesssim$ 30–40 MeV. See their Fig. 6 for mass-dependent limits.
[6] AGUILAR-AREVALO 21A quoted limit applies to m_{X^0} = 33.9 MeV. Limits between 4.3×10^{-6} and 7.5×10^{-5} are obtained for $0 < m_{X^0} <$ 33.9 MeV. The lifetime of X^0 is assumed to be long enough. See their Fig. 6 for mass-dependent limits.
[7] AGUILAR-AREVALO 21A quoted limit applies to m_{X^0} = 85 MeV. Limits between 5.2×10^{-8} and 1.4×10^{-6} are obtained for $0 < m_{X^0} <$ 120 MeV, which improve the limits of PICCIOTTO 88 by an order of magnitude. The lifetime of X^0 is assumed to be long enough. See their Fig. 4 for mass-dependent limits.
[8] AGUILAR-AREVALO 20 obtained limits of order 10^{-5} for m_{X^0} = 47.8–95.1 MeV. The quoted limit applies to m_{X^0} = 75 MeV. See their Fig. 1 for mass-dependent limits.
[9] BALDINI 20 obtained limits for m_{X^0} = 20–45 MeV and $\tau_{X^0} <$ 40 ps, and supersedes BOLTON 88 for m_{X^0} = 20–40 MeV. See their Fig. 17 for mass-dependent limits.
[10] BAYES 15 limits are the average over m_{X^0} = 13–80 MeV for the isotropic decay distribution of positrons. See their Fig. 4 and Table II for the mass-dependent limits as well as the dependence on the decay anisotropy. In particular, they find a limit $< 58\times10^{-6}$ at 90% CL for massless familons and for the same asymmetry as normal muon decay, a case not covered by JODIDIO 86.
[11] LATTANZI 13 use WMAP 9 year data as well as X-ray and γ-ray observations to derive limits on decaying majoron dark matter. A limit on the decay width $\Gamma(X^0 \to \nu\overline{\nu})$ $< 6.4\times10^{-19}$ s^{-1} at 95% CL is found if majorons make up all of the dark matter.
[12] LESSA 07 consider decays of the form Meson $\to \ell\nu$Majoron and $\ell \to \ell'\nu\overline{\nu}$Majoron and use existing data to derive limits on the neutrino-Majoron Yukawa couplings $g_{\alpha\beta}$ ($\alpha,\beta = e,\mu,\tau$). Their best limits are $|g_{e\alpha}|^2 < 5.5\times10^{-6}$, $|g_{\mu\alpha}|^2 < 4.5\times10^{-5}$, $|g_{\tau\alpha}|^2 < 5.5\times10^{-2}$ at CL = 90%.
[13] FARZAN 03 set limits on the neutrino Majoron Yukawa coupling, $|g_{ee}| < 4\times10^{-7}$, by considering the SN cooling due to the massless Majoron emission via neutrino coalescence. They also exclude values around 10^{-5} for both $g_{e\mu}$ and $g_{\mu\mu}$ using the process $\nu\nu \to X^0X^0$. See also their Figs. 3 and 4 for mass-dependent limits.
[14] DIAZ 98 studied models of spontaneously broken lepton number with both singlet and triplet Higgses. They obtain limits on the parameter space from invisible decay $Z \to H^0A^0 \to X^0X^0X^0X^0X^0$ and $e^+e^- \to ZH^0$ with $H^0 \to X^0X^0$.
[15] BOBRAKOV 91 searched for anomalous magnetic interactions between polarized electrons expected from the exchange of a massless pseudoscalar boson (arion). A limit $x_e^2 < 2\times10^{-4}$ (95%CL) is found for the effective anomalous magneton parametrized as $x_e(G_F/8\pi\sqrt{2})^{1/2}$.
[16] ALBRECHT 90E limits are for B($\tau \to \ell X^0$)/B($\tau \to \ell\nu\overline{\nu}$). Valid for $m_{X^0} <$ 100 MeV. The limits rise to 7.1% (for μ), 5.0% (for e) for m_{X^0} = 500 MeV.
[17] ATIYA 90 limit is for m_{X^0} = 0. The limit B $< 1\times10^{-8}$ holds for $m_{X^0} <$ 95 MeV. For the reduction of the limit due to finite lifetime of X^0, see their Fig. 3.
[18] BALKE 88 limits are for B($\mu^+ \to e^+ X^0$). Valid for $m_{X^0} <$ 80 MeV and $\tau_{X^0} > 10^{-8}$ sec.
[19] BOLTON 88 limit corresponds to $F > 3.1\times10^9$ GeV, which does not depend on the chirality property of the coupling.
[20] CHANDA 88 find $v_T <$ 10 MeV for the weak-triplet Higgs vacuum expectation value in Gelmini-Roncadelli model, and $v_S > 5.8\times10^6$ GeV in the singlet Majoron model.
[21] CHOI 88 used the observed neutrino flux from the supernova SN1987A to exclude the neutrino Majoron Yukawa coupling h in the range $2\times10^{-5} < h < 3\times10^{-4}$ for the interaction $L_{\rm int} = \frac{1}{2} i h \overline{\psi^c_\nu} \gamma_5 \psi_\nu \phi_X$. For several families of neutrinos, the limit applies for $(\Sigma h_i^4)^{1/4}$.
[22] PICCIOTTO 88 limit applies when $m_{X^0} <$ 55 MeV and $\tau_{X^0} >$ 2ns, and it decreases to 4×10^{-7} at m_{X^0} = 125 MeV, beyond which no limit is obtained.
[23] GOLDMAN 87 limit corresponds to $F > 2.9\times10^9$ GeV for the family symmetry breaking scale from the Lagrangian $L_{\rm int} = (1/F)\overline{\psi}_\mu\gamma^\mu\,(a+b\gamma_5)\,\psi_e\partial_\mu\phi_{X^0}$ with $a^2+b^2 = 1$. This is not as sensitive as the limit $F > 9.9\times10^9$ GeV derived from the search for $\mu^+ \to e^+X^0$ by JODIDIO 86, but does not depend on the chirality property of the coupling.
[24] Limits are for $\Gamma(\mu \to eX^0)/\Gamma(\mu \to e\nu\overline{\nu})$. Valid when m_{X^0} = 0–93.4, 98.1–103.5 MeV.
[25] EICHLER 86 looked for $\mu^+ \to e^+X^0$ followed by $X^0 \to e^+e^-$. Limits on the branching fraction depend on the mass and and lifetime of X^0. The quoted limits are valid when $\tau_{X^0} \lesssim 3.\times10^{-10}$ s if the decays are kinematically allowed.
[26] JODIDIO 86 corresponds to $F > 9.9\times10^9$ GeV for the family symmetry breaking scale with the parity-conserving effective Lagrangian $L_{\rm int} = (1/F)\,\overline{\psi}_\mu\gamma^\mu\psi_e\partial^\mu\phi_{X^0}$.
[27] BALTRUSAITIS 85 search for light Goldstone boson(X^0) of broken U(1). CL = 95% limits are B($\tau \to \mu^+X^0$)/B($\tau \to \mu^+\nu\nu$) <0.125 and B($\tau \to e^+X^0$)/B($\tau \to e^+\nu\nu$) <0.04. Inferred limit for the symmetry breaking scale is $m >$3000 TeV.
[28] The primordial heavy neutrino must decay into ν and familon, f_A, early so that the red-shifted decay products are below critical density, see their table. In addition, $K \to \pi f_A$ and $\mu \to e f_A$ are unseen. Combining these excludes $m_{{\rm heavy}\nu}$ between 5×10^{-5} and 5×10^{-4} MeV (μ decay) and $m_{{\rm heavy}\nu}$ between 5×10^{-5} and 0.1 MeV (K-decay).

Majoron Searches in Neutrinoless Double β Decay

Limits are for the half-life of neutrinoless $\beta\beta$ decay with a Majoron emission. No experiment currently claims any such evidence. Only the best or comparable limits for each isotope are reported.

[1] BERNATOWICZ 92 studied double-β decays of ^{128}Te and ^{130}Te, and found the ratio $\tau(^{130}\text{Te})/\tau(^{128}\text{Te}) = (3.52 \pm 0.11) \times 10^{-4}$ in agreement with relatively stable theoretical predictions. The bound is based on the requirement that Majoron-emitting decay cannot be larger than the observed double-beta rate of ^{128}Te of $(7.7 \pm 0.4) \times 10^{24}$ year. We calculated 90% CL limit as $(7.7\text{–}1.28 \times 0.4 = 7.2) \times 10^{24}$.

[2] AZZOLINI 23 use 9.95 kg·yr of data, collected by the CUPID-0 experiment, to place a limit on the single Majoron mode of the $0\nu\beta\beta$ decay of ^{82}Se. Various limits on modes involving the emission of multiple Majorons are given too. The resulting constraint on the Majoron-neutrino coupling constant is $g_{\nu\chi} < 1.8\text{–}4.4 \times 10^{-5}$. The range is due to the variability of the used nuclear matrix elements.

[3] AGOSTINI 22 use 32.8 kg·yr of GERDA phase 2 data to derive a limit of $g_{\nu\chi} < 1.8\text{–}4.4 \times 10^{-5}$ on the neutrino-Majoron coupling. The range reflects the author's evaluation of the spread of nuclear matrix elements.

[4] AL-KHARUSI 21 utilize the complete dataset of the EXO-200 experiment, corresponding to an exposure of 234 kg yr, to place a limit on the one Majoron mode of the neutrinoless double beta decay of ^{136}Xe. Several limits are reported, the one given here corresponds to a spectral index of 1, resulting in a limit of $g_{\nu\chi} < 0.4\text{–}0.9 \times 10^{-5}$ on the Majoron-neutrino coupling constant. The range reflects the spread of the nuclear matrix elements.

[5] ARNOLD 19 uses the NEMO-3 tracking calorimeter to determine limits for the Majoron emitting double beta decay, with spectral index n = 3. The limit corresponds to the range of the g_{ee} coupling of 0.013–0.035; dependimg on the nuclear matrix elements used.

[6] ARNOLD 18 use the NEMO-3 tracking detector. The limit corresponds to $\langle g_{ee} \rangle < 3.2\text{–}8.0 \times 10^{-5}$; the range corresponds to different nuclear matrix element calculations.

[7] AGOSTINI 15A analyze a 20.3 kg yr of data set of the GERDA calorimeter to determine $g_{\nu\chi} < 3.4\text{–}8.7 \times 10^{-5}$ on the Majoron-neutrino coupling constant. The range reflects the spread of the nuclear matrix elements.

[8] ARNOLD 15 use the NEMO-3 tracking calorimeter with 3.43 kg yr exposure to determine the limit on Majoron emission. The limit corresponds to $g_{\nu\chi} < 1.6\text{–}3.0 \times 10^{-4}$. The spread reflects different nuclear matrix elements. Supersedes ARNOLD 06.

[9] ALBERT 14A utilize 100 kg yr of exposure of the EXO-200 tracking calorimeter to place a limit on the $g_{\nu\chi} < 0.8\text{–}1.7 \times 10^{-5}$ on the Majoron-neutrino coupling constant. The range reflects the spread of the nuclear matrix elements.

[10] GANDO 12 use the KamLAND-Zen detector to obtain the limit on the $0\nu\chi$ decay with Majoron emission. It implies that the coupling constant $g_{\nu\chi} < 0.8\text{–}1.6 \times 10^{-5}$ depending on the nuclear matrix elements used.

[11] ARNOLD 11 use the NEMO-3 detector to obtain the reported limit on Majoron emission. It implies that the coupling constant $g_{\nu\chi} < 0.6\text{–}1.6 \times 10^{-4}$ depending on the nuclear matrix element used. Supercedes ARNABOLDI 03.

[12] ARGYRIADES 10 use the NEMO-3 tracking detector and ^{96}Zr to derive the reported limit. No limit for the Majoron electron coupling is given.

[13] ARGYRIADES 09 use ^{150}Nd data taken with the NEMO-3 tracking detector. The reported limit corresponds to $\langle g_{\nu\chi} \rangle < 1.7\text{–}3.0 \times 10^{-4}$ using a range of nuclear matrix elements that include the effect of nuclear deformation.

[14] ARNOLD 06 use ^{100}Mo data taken with the NEMO-3 tracking detector. The reported limit corresponds to $\langle g_{\nu\chi} \rangle < (0.4\text{–}1.8) \times 10^{-4}$ using a range of matrix element calculations. Superseded by ARNOLD 15.

[15] NEMO-3 tracking calorimeter is used in ARNOLD 06 . Reported half-life limit for ^{82}Se corresponds to $\langle g_{\nu\chi} \rangle < (0.66\text{–}1.9) \times 10^{-4}$ using a range of matrix element calculations. Supersedes ARNOLD 04.

[16] ARNOLD 04 use the NEMO-3 tracking detector. The limit corresponds to $\langle g_{\nu\chi} \rangle < (0.5\text{–}0.9)10^{-4}$ using the matrix elements of SIMKOVIC 99, STOICA 01 and CIVITARESE 03. Superseded by ARNOLD 06.

[17] ARNOLD 04 use the NEMO-3 tracking detector. The limit corresponds to $\langle g_{\nu\chi} \rangle < (0.7\text{–}1.6)10^{-4}$ using the matrix elements of SIMKOVIC 99, STOICA 01 and CIVITARESE 03.

[18] Supersedes ALESSANDRELLO 00. Array of TeO_2 crystals in high resolution cryogenic calorimeter. Some enriched in ^{130}Te. Derive $\langle g_{\nu\chi} \rangle < 17\text{–}33 \times 10^{-5}$ depending on matrix element.

[19] Supersedes ALESSANDRELLO 00. Cryogenic calorimeter search.

[20] Limit for the $0\nu\chi$ decay with Majoron emission of ^{116}Cd using enriched $CdWO_4$ scintillators. $\langle g_{\nu\chi} \rangle < 4.6\text{–}8.1 \times 10^{-5}$ depending on the matrix element. Supersedes DANEVICH 00.

[21] Limit for the $0\nu2\chi$ decay of ^{116}Cd. Supersedes DANEVICH 00.

[22] BERNABEI 02D obtain limit for $0\nu\chi$ decay with Majoron emission of ^{136}Xe using liquid Xe scintillation detector. They derive $\langle g_{\nu\chi} \rangle < 2.0\text{–}3.0 \times 10^{-5}$ with several nuclear matrix elements.

[23] Replaces TANAKA 93. FUSHIMI 02 derive half-life limit for the $0\nu\chi$ decay by means of tracking calorimeter ELEGANT V. Considering various matrix element calculations, a range of limits for the Majoron-neutrino coupling is given: $\langle g_{\nu\chi} \rangle < (6.3\text{–}360) \times 10^{-5}$.

[24] ASHITKOV 01 result for $0\nu\chi$ of ^{100}Mo is less stringent than ARNOLD 00.

[25] DANEVICH 01 obtain limit for the $0\nu\chi$ decay with Majoron emission of ^{160}Gd using Gd_2SiO_5:Ce crystal scintillators.

[26] DANEVICH 01 obtain limit for the $0\nu2\chi$ decay with 2 Majoron emission of ^{160}Gd.

[27] ARNOLD 00 reports limit for the $0\nu\chi$ decay with Majoron emission derived from tracking calorimeter NEMO 2. Using ^{82}Se source: $\langle g_{\nu\chi} \rangle < 1.6 \times 10^{-4}$. Matrix element from GUENTHER 96.

[28] Using ^{96}Zr source: $\langle g_{\nu\chi} \rangle < 2.6 \times 10^{-4}$. Matrix element from ARNOLD 99.

[29] ARNOLD 00 reports limit for the $0\nu2\chi$ decay with two Majoron emission derived from tracking calorimeter NEMO 2.

[30] ARNOLD 98 determine the limit for $0\nu_\chi$ decay with Majoron emission of ^{82}Se using the NEMO-2 tracking detector. They derive $\langle g_{\nu_\chi} \rangle < 2.3\text{–}4.3 \times 10^{-4}$ with several nuclear matrix elements.

[31] LUESCHER 98 report a limit for the 0ν decay with Majoron emission of ^{136}Xe using Xe TPC. This result is more stringent than BARABASH 89. Using the matrix elements of ENGEL 88, they obtain a limit on $\langle g_{\nu\chi} \rangle$ of 2.0×10^{-4}.

[32] See Table 1 in GUENTHER 96 for limits on the Majoron coupling in different models.

Invisible A^0 (Axion) MASS LIMITS from Astrophysics and Cosmology

$v_1 = v_2$ is usually assumed (v_i = vacuum expectation values). For a review of these limits, see RAFFELT 91 and TURNER 90. In the comment lines below, D and K refer to DFSZ and KSVZ axion types, discussed in the above minireview.

[1] CHENG 23 employ an improved approximation of the boson cloud eigenfrequency to calculate the superradiance rate. They find that sensitivity depends on initial spin distribution and the merger timescale, and identify two preferred ranges for boson mass centered at 1.78×10^{-12} and 7.94×10^{-13} eV.

[2] DELLA-MONICA 23 consider the solitonic core implied by ultralight scalar dark matter in the centre of the Milky Way and the effect its presence would have on the precisely tracked orbits of the stars orbiting our galaxy's central supermassive black hole, Sagittarius A*.

[3] DERBIN 23 employ a thulium garnet crystal bolometer to search for the 8.4 keV solar axion line emitted from the M1 nuclear transition of thulium-169, ^{169}Tm. Mass bound applies to KSVZ axions, value for DFSZ is 244 eV.

[4] NOTARI 23 improved the evaluation of axion production from pion scatterings by using pion–pion scattering data and incorporating the momentum dependence of the Boltzmann equation. The limit is based on the Planck 2018, BAO, and Pantheon SN Ia data.

[5] ROGERS 23 use the CMB and BOSS galaxy-clustering data to set limits on the abundance of ultralight axion DM. They obtained $\Omega_{A^0} < 0.002$ for $m_{A^0} = 10^{-30}$–10^{-28} eV and set upper limits ranging from 0.002 to 0.07 for $m_{A^0} = 10^{-32}$–10^{-25} eV. See their Fig. 22 for mass-dependent limits.

[6] SMARRA 23 is the European Pulsar Timing Array's constraint on the contribution of ultralight DM to the DM density in our local galactic neighbourhood. Ultralight DM cannot saturate the known DM density of 0.3 GeV/cc for masses inside this mass interval of 10^{-24}–5×10^{-23} eV.

[7] XIA 23 is analogous to PORAYKO 18 and use the Fermi-LAT pulsar timing array. They set a bound on the local density as $\rho_{A^0} \lesssim 8$ GeV/cm^3 for $m_{A^0} \lesssim 10^{-23}$ eV at 95% CL, with weaker constraints up to 10^{-22} eV. See their Fig. 1 for the mass-dependent limits.

[8] LAGUE 22 used the BOSS galaxy-clustering data to set limits on the abundance of ultralight axion dark matter. When combined with the CMB data, they obtained $\Omega_{A^0}h^2 < 0.004$ for $m_{A^0} = 10^{-31}$–10^{-26} eV. See their Figs. 1 and 15 for mass-dependent limits.

[9] YUAN 22A use the data of Advanced LIGO and Advanced Virgo's first three observing runs to search for stochastic GW background produced by scalar bosonic clouds formed by the BH superradiant instability. They set the limit, taking into account all the unstable modes.

[10] BANIK 21 use the subhalo mass function inferred from the analyses of the GD-1 and Pal 5 stellar streams. The limit is strengthened to 2.2×10^{-21} eV when adding dwarf satellite counts.

[11] BAUMHOLZER 21 study the freeze-in production of axion dark matter through couplings to photons, and set the limit using Lyman-α forest data and the observed number of Milky Way subhalos.

[12] CROON 21 study the supernova cooling effect of the axion-muon coupling, taking account of semi-Compton scattering and muon-proton bremsstrahlung, as well as the loop-induced axion-photon coupling, and exclude the range of $g_{A\mu\mu} \simeq 7\times10^{-3}$–$2\times10^{-10}$ for $m_{A^0} < 0.5$ GeV. See their Fig. 8 for mass-dependent limits.

[13] FUJIKURA 21 use the EROS-2 survey and the Subaru HSC observation to set limits on spherically symmetric axion clumps, taking account of the finite lens and source size effects. $f_{A^0} \gtrsim 10^{12}$ GeV can be constrained depending on the fraction of the axion dark matter collapsed into clumps, and the clump densities. See their Figs. 7–10 for the limits.

[14] MARTINCAMALICH 21 considered axion emission from a supernova core through the Λ hyperon decay, and set the limit on B($\Lambda \to nA^0$) $\lesssim 8\times10^{-9}$, or equivalently, $f_{A^0}/C_{sd} \gtrsim 2.6\times10^9$ GeV in terms of the flavor-violating axion coupling to the down and strange quarks.

[15] NG 21 use the binary black holes reported by LIGO and Virgo to determine the black hole spin distribution at formation and the scalar boson mass simultaneously, neglecting the boson self-interaction.

[16] ROGERS 21 set the limit by using a framework involving Bayesian emulator optimization to accurately forward-model the Lyman-α flux power spectrum, and comparing this with small-scale data to constrain the predicted suppression of cosmic structure growth.

[17] TSUKADA 21 look for a stochastic GW background produced by extragalactic BH-hidden photon cloud systems through the superradiant instability. They assume a uniform spin distribution at birth of isolated BHs from 0 to 1.

[18] IRSIC 20 used the Lyman-α forest constraint on small-scale isocurvature perturbation to derive limits on the axion mass and decay constant, assuming that the axion makes up all dark matter in the post-inflationary scenario. See their Fig. 1 for other astrophysical limits as well as the limits on the case of the temperature-dependent axion mass.

[19] PODDAR 20 used the observed decay in orbital period of four compact binary systems to derive a limit on the emission of axions with $m_{A^0} < 1\times10^{-19}$ eV, assuming they couple to nucleons and the strong CP phase vanishes at the potential minimum. They exclude $f_{A^0} \lesssim 10^{11}$ GeV for such axions.

[20] SCHUTZ 20 set a limit on fuzzy dark matter based on the existing limits for warm dark matter derived from the inferred subhalo mass function.

[21] SUN 20 look for quasimonochromatic gravitational waves emitted from boson clouds around the Cygnus X-1 black hole. The quoted limit assume the black hole age of 5×10^6 years. A mass range of 9.6–15.5 $\times10^{-13}$ eV is disfavored when repeated induction of bosenova for string axions with decay constant $f_{A^0} \simeq 10^{15}$ GeV prevents the superradiance from being saturated.

[22] DAVOUDIASL 19 used the observed data of M87* by the Event Horizon Telescope to set the limit. A mass range of 0.85–4.6×10^{-21} eV is disfavored for a spin-1 boson.

[23] MARSH 19 considered heating of star clusters due to the stochastic oscillations of the core and granular quasiparticles in the outer halo. The limit was derived by requiring the survival of the old star cluster in Eridanus II, where the lower end is set by the validity of diffusion approximation. The effect of tidal stripping is also discussed for lower masses.

[24] PALOMBA 19 used the LIGO O2 dataset to derive limits on nearly monochromatic gravitational waves emitted by boson clouds formed around a stellar-mass black hole. They exclude boson masses in a range of 1.1×10^{-13} and 4×10^{-13} eV for high initial black hole spin, and 1.2×10^{-13} and 1.8×10^{-13} eV for moderate spin. See their Figs. 2 and 3 for limits based on various values of black hole initial spin, boson cloud age, and distance.

[25] CHANG 18 update axion bremsstrahlung emission rates in nucleon–nucleon collisions, shifting the excluded mass range to higher values. They rule out the hadronic axion with mass up to a few hundred eV, closing the hadronic axion window. See their Fig. 11 for results based on several different choices of the temperature and density profile of the proto-neutron star.

[26] PORAYKO 18 look for time-dependent oscillations in the gravitational potential generated by ultralight scalar dark matter, and set a bound on its local density as $\rho_{A^0} \lesssim 6$ GeV/cm^3 for $m_{A^0} \lesssim 10^{-23}$ eV at 95% CL. See their Fig. 4 for the limits.

[27] ARCHIDIACONO 13A is analogous to HANNESTAD 05A. The limit is based on the CMB temperature power spectrum of the Planck data, the CMB polarization from the WMAP 9-yr data, the matter power spectrum from SDSS-DR7, and the local Hubble parameter measurement by the Carnegie Hubble program.

[28] CADAMURO 11 use the deuterium abundance to show that the m_{A^0} range 0.7 eV – 300 keV is excluded for axions, complementing HANNESTAD 10.

[29] DERBIN 11A look for solar axions produced by Compton and bremsstrahlung processes, in the resonant excitation of ^{169}Tm, constraining the axion-electron $\times$ axion nucleon couplings.

[30] ANDRIAMONJE 10 search for solar axions produced from ^{7}Li (478 keV) and D(p,γ)^{3}He (5.5 MeV) nuclear transitions. They show limits on the axion-photon coupling for two reference values of the axion-nucleon coupling for $m_A < 100$ eV.

[31] This is an update of HANNESTAD 08 including 7 years of WMAP data.

[32] ANDRIAMONJE 09 look for solar axions produced from the thermally excited 14.4 keV level of ^{57}Fe. They show limits on the axion-nucleon $\times$ axion-photon coupling assuming $m_A < 0.03$ eV.

[33] DERBIN 09A look for Primakoff-produced solar axions in the resonant excitation of ^{169}Tm, constraining the axion-photon $\times$ axion-nucleon couplings.

[34] KEKEZ 09 look at axio-electric effect of solar axions in HPGe detectors. The one-loop axion-electron coupling for hadronic axions is used.

[35] This is an update of HANNESTAD 07 including 5 years of WMAP data.

[36] This is an update of HANNESTAD 05A with new cosmological data, notably WMAP (3 years) and baryon acoustic oscillations (BAO). Lyman-α data are left out, in contrast to HANNESTAD 05A and MELCHIORRI 07A, because it is argued that systematic errors are large. It uses Bayesian statistics and marginalizes over a possible neutrino hot dark matter component.

[37] MELCHIORRI 07A is analogous to HANNESTAD 05A, with updated cosmological data, notably WMAP (3 years). Uses Bayesian statistics and marginalizes over a possible neutrino hot dark matter component. Leaving out Lyman-α data, a conservative limit is 1.4 eV.

[38] HANNESTAD 05A puts an upper limit on the mass of hadronic axion because in this mass range it would have been thermalized and contribute to the hot dark matter component of the universe. The limit is based on the CMB anisotropy from WMAP, SDSS large scale structure, Lyman α, and the prior Hubble parameter from HST Key Project. A χ^2 statistic is used. Neutrinos are assumed not to contribute to hot dark matter.

[39] MOROI 98 points out that a KSVZ axion of this mass range (see CHANG 93) can be a viable hot dark matter of Universe, as long as the model-dependent $g_{A\gamma}$ is accidentally small enough as originally emphasized by KAPLAN 85; see Fig. 1.

[40] BORISOV 97 bound is on the axion-electron coupling $g_{ae} < 1\times10^{-13}$ from the photo-production of axions off of magnetic fields in the outer layers of neutron stars.

[41] KACHELRIESS 97 bound is on the axion-electron coupling $g_{ae} < 1\times10^{-10}$ from the production of axions in strongly magnetized neutron stars. The authors also quote a stronger limit, $g_{ae} < 9\times10^{-13}$ which is strongly dependent on the strength of the magnetic field in white dwarfs.

[42] KEIL 97 uses new measurements of the axial-vector coupling strength of nucleons, as well as a reanalysis of many-body effects and pion-emission processes in the core of the neutron star, to update limits on the invisible-axion mass.

[43] RAFFELT 95 reexamined the constraints on axion emission from red giants due to the axion-electron coupling. They improve on DEARBORN 86 by taking into proper account degeneracy effects in the bremsstrahlung rate. The limit comes from requiring the red giant core mass at helium ignition not to exceed its standard value by more than 5% (0.025 solar masses).

[44] ALTHERR 94 bound is on the axion-electron coupling $g_{ae} < 1.5\times10^{-13}$, from energy loss via axion emission.

[45] CHANG 93 updates ENGEL 90 bound with the Kaplan-Manohar ambiguity in $z=m_u/m_d$ (see the Note on the Quark Masses in the Quark Particle Listings). It leaves the window f_A=3×10^5–3×10^6 GeV open. The constraint from Big-Bang Nucleosynthesis is satisfied in this window as well.

[46] BERSHADY 91 searched for a line at wave length from 3100–8300 Å expected from 2γ decays of relic thermal axions in intergalactic light of three rich clusters of galaxies.

[47] KIM 91C argues that the bound from the mass density of the universe will change drastically for the supersymmetric models due to the entropy production of saxion (scalar component in the axionic chiral multiplet) decay. Note that it is an *upperbound* rather than a lowerbound.

[48] RAFFELT 91B argue that previous SN 1987A bounds must be relaxed due to corrections to nucleon bremsstrahlung processes.

[49] RESSELL 91 uses absence of any intracluster line emission to set limit.

[50] ENGEL 90 rule out $10^{-10} \lesssim g_{AN} \lesssim 10^{-3}$, which for a hadronic axion with EMC motivated axion-nucleon couplings corresponds to 2.5×10^{-3} eV $\lesssim m_{A^0} \lesssim 2.5\times10^4$ eV. The constraint is loose in the middle of the range, i.e. for $g_{AN} \sim 10^{-6}$.

[51] RAFFELT 90D is a re-analysis of DEARBORN 86.

[52] The region $m_{A^0} \gtrsim 2$ eV is also allowed.

[53] ERICSON 89 considered various nuclear corrections to axion emission in a supernova core, and found a reduction of the previous limit (MAYLE 88) by a large factor.

[54] MAYLE 89 limit based on naive quark model couplings of axion to nucleons. Limit based on couplings motivated by EMC measurements is 2–4 times weaker. The limit from axion-electron coupling is weak: see HATSUDA 88B.

[55] RAFFELT 88B derives a limit for the energy generation rate by exotic processes in helium-burning stars $\epsilon < 100$ erg g^{-1} s^{-1}, which gives a firmer basis for the axion limits based on red giant cooling.

[56] RAFFELT 87 also gives a limit $g_{A\gamma} < 1\times10^{-10}$ GeV^{-1}.

[57] DEARBORN 86 also gives a limit $g_{A\gamma} < 1.4\times10^{-11}$ GeV^{-1}.

[58] RAFFELT 86 gives a limit $g_{A\gamma} < 1.1\times10^{-10}$ GeV^{-1} from red giants and $< 2.4\times10^{-9}$ GeV^{-1} from the sun.

[59] KAPLAN 85 says $m_{A^0} < 23$ eV is allowed for a special choice of model parameters.

[60] FUKUGITA 82 gives a limit $g_{A\gamma} < 2.3\times10^{-10}$ GeV^{-1}.

Search for Relic Invisible Axions

Limits are for the dimensionless quantity $[G_{A\gamma\gamma}/m_{A0}]^2\rho_A$ where $G_{A\gamma\gamma}$ denotes the axion two-photon coupling, $L_{\rm int} = -\frac{G_{A\gamma\gamma}}{4}\phi_A F_{\mu\nu}\tilde{F}^{\mu\nu} = G_{A\gamma\gamma}\phi_A \mathbf{E}\cdot\mathbf{B}$, and ρ_A is the axion energy density near the earth, unless otherwise stated. Notice that for QCD axions $G_{A\gamma\gamma}/m_{A^0}$ does not depend on m_{A^0}. For the reference values $m_{A^0} = 1$ μeV, $G_{A\gamma\gamma} = 3.9\times10^{-16}$ GeV^{-1} (that would apply to KSVZ axions at that mass), and $\rho_A = 300$ MeV/cm^3 one finds $[G_{A\gamma\gamma}/m_{A^0}]^2\rho_A = 3.5\times10^{-43}$.

$<6.3\times10^{-42}$	95	[55] WUENSCH	89	CNTR	m_{A^0} = (4.5–10.2)10^{-6} eV
$<5.4\times10^{-41}$	95	[55] WUENSCH	89	CNTR	m_{A^0} = (11.3–16.3)10^{-6} eV

[1] ADACHI 23D is analogous to ADE 21. They used POLARBEAR data, and take account of a stochastic local axion field amplitude with the time-averaged local axion density ρ_A = 0.3 GeV/cm^3. Limits are set at $G_{A\gamma\gamma} < 2.4\times10^{-11}$ GeV^{-1} ($m_{A^0}/10^{-21}$ eV), which is 2.2 times larger than the deterministic case. See Fig. 5 for mass-dependent limits.

[2] DI-VORA 23 searches for axions in a narrow mass window using an 8T haloscope and a travelling wave parametric amplifier to achieve noise close to the quantum limit. This is an improvement on their previous scan at the same mass, ALESINI 21. See Fig. 7 for mass-dependent limits and a comparison.

[3] JEWELL 23 is an update of BRUBAKER 17. See their Fig. 11 for the mass-dependent limits.

[4] JEWELL 23 correct an underestimation of intermediate frequency noise in BACKES 21. See their Fig. 11 for the mass-dependent limits.

[5] KIM 23 is an update of KWON 21 on the CAPP-PACE experiment. See their Fig. 4 for mass-dependent limits.

[6] OSHIMA 23 report first limits from the DANCE experiment. This experiment is based on a novel bow-tie cavity design that searches for the oscillating rotation of polarised laser light driven by the DM axion-photon mixing at low frequencies. See their Fig. 6 for mass-dependent limits.

[7] THOMSON 23 used an AC microwave cavity to search for dark matter axions. The axion signal is resonantly enhanced when the axion mass matches the difference between a cavity which is pumped with power and another resonant mode close in frequency that is used to read out the signal. See their Fig. 7 for the mass-dependent limits.

[8] YANG 23 extends the first phase of CAPP 18T to KSVZ axions between 4.8077 and 4.8181 GHz. They used an 18T high-temperature superconducting magnet haloscope. See their Fig. 5 for mass-dependent limits. Quoted value is for their limit derived with a Bayesian method.

[9] YI 23 is analogous to LEE 20A, using the CAPP-12TB haloscope. See their Fig. 4 for mass-dependent limits.

[10] YI 23A used the same data as YI 23, but instead of the standard halo model, they searched for axion dark matter in the Sagittarius tidal stream with a velocity v = 300 km/sec and a velocity dispersion δv = 20 km/sec. See their Fig. 4 for mass-dependent limits.

[11] ADE 22 is an update of ADE 21 based on the expanded data of the 2012–2015 observing seasons. See their Fig. 3 for mass-dependent limits over the extended mass range 1×10^{-23}–6×10^{-19} eV.

[12] ALESINI 22 is an update of ALESINI 21, using the TM030 mode of the cylindrical dielectric cavity. See their Fig. 8 for mass-dependent limits.

[13] BATTYE 22 is analogous to DARLING 20A, and use plasma ray tracing technique to analyze the propagation of radio photons converted from axion dark matter in the magnetosphere of PSR J1745-2900. The quoted limit assumes $\rho_A = 6.5 \times 10^4$ GeV/cm^3 in the vicinity of the magnetar. See their Fig. 1 for mass-dependent limits.

[14] CHANG 22 used a microwave cavity detector to search for dark matter axions. See Fig. 3 for the mass-dependent limits.

[15] FERGUSON 22 is analogous to ADE 21. They use the data of the SPT-3G's 2019 observing season. See their Fig. 5 for mass-dependent limits over the extended mass range 0.047–9.5 $\times 10^{-20}$ eV.

[16] LEE 22 is analogous to LEE 20A. They used an 18T high-temperature superconducting magnet haloscope. See their Fig. 5 for mass-dependent limits.

[17] QUISKAMP 22 is a 15.28 to 16.23 GHz microwave cavity haloscope with 11.5 T B-field. See Fig. 4 for mass-dependent limits.

[18] YOON 22 analyzed the data from LEE 22 and changed from a frequentist to a Bayesian method to set limits. See their Fig. 27 for mass-dependent limits.

[19] ZHOU 22 is analogous to DARLING 20A, and they use the data from the MeerKAT radio telescope's observation of the neutron star J0806.4-4123, which is 250 pc from Earth. See their Fig.3 for mass-dependent limits.

[20] ADE 21 looks for a time-variable global rotation of the CMB polarization induced by the harmonic oscillations of local axion-like dark matter and uses data from the 2012 observing season of the Keck Array, part of the BICEP program. The limits get 25% weaker for $m_{A^0} = 4.8 \times 10^{-20}$–$5.7 \times 10^{-19}$ eV. See their Eq. (80) and Fig. 6 for mass-dependent limits.

[21] ALESINI 21 is an update of ALESINI 19. See their Figs. 5 and 6 for the mass-dependent limits.

[22] BARTRAM 21A is analogous to DU 18. See their Fig.4 for mass-dependent limits.

[23] DEVLIN 21 use the superconducting resonant detection circuit of a cryogenic Penning trap with a single antiproton. See their Fig. 3 for mass-dependent limits.

[24] GRAMOLIN 21 use two detection channels, each consisting of two stacked toroids to look for the axion-induced oscillating magnetic field. The quoted limit applies at $m_{A^0} = 0.02$ neV. See their Fig. 4 for mass-dependent limits.

[25] KWON 21 is analogous to LEE 20A. They also obtain weaker limits in the range of $m_{A^0} = 10.16$–11.37 μeV. See their Fig. 4 for mass-dependent limits.

[26] MELCON 21 use a radio frequency cavity consisting of 5 sub-cavities coupled by inductive irises installed inside the CAST dipole magnet to look for higher axion masses. See their Fig. 9 for mass-dependent limits.

[27] SALEMI 21 is an update of OUELLET 19A. See their Fig. 4 for mass-dependent limits.

[28] THOMSON 21 use a resonant cavity supporting two spatially overlapping microwave modes, which is sensitive to the axion mass corresponding to the sum or difference of the two resonant frequencies. The original limit was retracted due to a sign error. See their Fig. 2 in the erratum for the corrected limits.

[29] YUAN 21 use polarimetric observations of Sgr A* taken by the Event Horizon Telescope to search for periodic oscillation of the polarization induced by axion dark matter, assuming a solitonic core near the Galactic center. They obtained limits in the range of $G_{A\gamma\gamma} = 8 \times 10^{-13}$–$3 \times 10^{-11}$ GeV^{-1}.

[30] BRAINE 20 is analogous to DU 18. See Fig. 4 for their mass-dependent limits.

[31] CRISOSTO 20 used a resonant LC circuit to look for lighter axion dark matter. They obtained a similar, slightly weaker limit for $m_{A^0} = 174.98$–175.19 and 177.34–177.38 neV. See their Fig. 4 for mass-dependent limits.

[32] DARLING 20A use VLA data to look for radio-frequency radiation converted from axion dark matter in the magnetosphere of the Galactic Center magnetar PSR J1745-2900. They extended the results of DARLING 20, which used only data with the highest angular resolution, by adding sub-optimal data. They use $\rho_A = 6.5 \times 10^4$ GeV/cm^3 in the vicinity of the magnetar. See their Fig. 2 for mass-dependent limits.

[33] FOSTER 20 look for radio-frequency radiation converted from axion dark matter in the magnetic field around neutron stars. They use the observed data of isolated local neutron stars and in the Galactic center. The quoted limit applies to $m_{A^0} \simeq 7$ μeV. See their Fig. 2 for mass-dependent limits.

[34] JEONG 20 is analogous to LEE 20A, and they use a double-cell cavity to look for axions with mass > 10 μeV. See their Fig. 5 for mass-dependent limits.

[35] KENNEDY 20 is analogous to BRANCA 17, and they compare the frequency ratios of the Si cavity measured by a Sr optical lattice clock and by a H maser. Assuming the local density of moduli dark matter, $\rho_S = 0.3$ GeV/cm^3, they obtain a limit $G_{S\gamma\gamma} < 5.8 \times 10^{-24}$ GeV^{-1} at $m_{S^0} = 2 \times 10^{-19}$ eV. See their Fig. 2 for mass-dependent limits as well as limits on the modulus coupling to electrons.

[36] LEE 20A used a microwave cavity detector at the IBS/CAPP to search for dark matter axions. See Fig. 3 for the mass-dependent limits.

[37] ALESINI 19 used a superconducting resonant cavity made of NbTi to increase the quality factor. The limit applies to a mass range of 0.2 neV around $m_{A^0} = 37.5$ μeV.

[38] FUJITA 19 look for photon birefringence under the oscillating axion background using the polarimetric imaging observation of a protoplanetary disk, AB Aur. See their Fig. 2 for a more conservative limit taking account of possible systematic effects.

[39] OUELLET 19A look for the axion-induced oscillating magnetic field generated by a toroidal magnetic field. The quoted limit applies at $m_{A^0} = 8$ neV. See their Fig. 3 for the mass-dependent limits.

[40] BOUTAN 18 use a small high frequency cavity installed above the main ADMX cavity to look for heavier axion dark matter. See their Fig. 4 for mass-dependent limits.

[41] DU 18 is analogous to DUFFY 06. They upgraded a dilution refrigerator to reduce the system noise. The quoted limit is around $m_{A^0} = 2.69$ μeV for the boosted Maxwellian axion line shape. See Fig. 4 for their mass-dependent limits.

[42] ZHONG 18 is analogous to BRUBAKER 17. The quoted limit applies at $m_{A^0} = 23.76$ μeV. See Fig. 4 for their mass-dependent limits.

[43] BRANCA 17 look for modulations of the fine-structure constant and the electron mass due to moduli dark matter by using the cryogenic resonant-mass AURIGA detector. The limit on the assumed dilatonic coupling implies $G_{S\gamma\gamma} < 1.5 \times 10^{-24}$ GeV^{-1} for the scalar to two-photon coupling. See Fig. 5 for the mass-dependent limits.

[44] BRUBAKER 17 used a microwave cavity detector at the Yale Wright Laboratory to search for dark matter axions. See Fig. 3 for the mass-dependent limits.

[45] CHOI 17 used a microwave cavity detector with toroidal geometry. See Fig. 4 for their mass-dependent limits.

[46] MCALLISTER 17 used a high-frequency microwave cavity haloscope at 26.6 GHz in a 7 T magnetic field. See Fig. 4 for mass-dependent limits.

[47] HOSKINS 16 is analogous to DUFFY 06. See Fig. 12 for mass-dependent limits in terms of the local dark matter density.

[48] BECK 13 argues that dark-matter axions passing through Earth may generate a small observable signal in resonant S/N/S Josephson junctions. A measurement by HOFFMANN 04 [Physical Review **B70** 180503 (2004)] is interpreted in terms of subdominant dark matter axions with $m_{A^0} = 0.11$ meV.

[49] HOSKINS 11 is analogous to DUFFY 06. See Fig. 4 for the mass-dependent limit in terms of the local density.

[50] ASZTALOS 10 used the upgraded detector of ASZTALOS 04 to search for halo axions. See their Fig. 5 for the m_{A^0} dependence of the limit.

[51] DUFFY 06 used the upgraded detector of ASZTALOS 04, while assuming a smaller velocity dispersion than the isothermal model as in Eq. (8) of their paper. See Fig. 10 of their paper on the axion mass dependence of the limit.

[52] ASZTALOS 04 looked for a conversion of halo axions to microwave photons in magnetic field. At 90% CL, the KSVZ axion cannot have a local halo density more than 0.45 GeV/cm^3 in the quoted mass range. See Fig. 7 of their paper on the axion mass dependence of the limit.

[53] KIM 98 calculated the axion-to-photon couplings for various axion models and compared them to the HAGMANN 90 bounds. This analysis demonstrates a strong model dependence of $G_{A\gamma\gamma}$ and hence the bound from relic axion search.

[54] HAGMANN 90 experiment is based on the proposal of SIKIVIE 83.

[55] WUENSCH 89 looks for condensed axions near the earth that could be converted to photons in the presence of an intense electromagnetic field via the Primakoff effect, following the proposal of SIKIVIE 83. The theoretical prediction with $[G_{A\gamma\gamma}/m_{A^0}]^2 = 2 \times 10^{-14}$ MeV^{-4} (the three generation DFSZ model) and $\rho_A = 300$ MeV/cm^3 that makes up galactic halos gives $(G_{A\gamma\gamma}/m_{A^0})^2\, \rho_A = 4 \times 10^{-44}$. Note that our definition of $G_{A\gamma\gamma}$ is $(1/4\pi)$ smaller than that of WUENSCH 89.

Invisible A^0 (Axion) Limits from Photon Coupling

Limits are for the modulus of the axion-two-photon coupling $G_{A\gamma\gamma}$ defined by $L = -G_{A\gamma\gamma}\phi_A \mathbf{E}\cdot\mathbf{B}$. For scalars S^0 the limit is on the coupling constant in $L = G_{S\gamma\gamma}\phi_S(\mathbf{E}^2 - \mathbf{B}^2)$. The relation between $G_{A\gamma\gamma}$ and m_{A^0} is not used unless stated otherwise, i.e., many of these bounds apply to low-mass axion-like particles (ALPs), not to QCD axions.

[1] PANT 24 searches for the imprint of axion-photon oscillations in the very-high-energy gamma-ray spectrum of the quasar QSO B1420+326 observed by the MAGIC telescope. Three small disconnected regions of mass-coupling parameter space below 1 neV are ruled out. See Fig. 4 for the limits.

[2] BATTYE 23 look for dark-matter axions falling into pulsar magnetospheres and converting into narrow radio lines. Unlike the earlier FOSTER 22 they search for evidence of conversion in the time-domain signal of a single pulsar, using 1 hour of MeerKAT data on the pulsar PSR J2144-3933. The quoted limit applies to an assumed magnetic field of 2×10^{12} G and a dark matter density of 0.45 GeV/cm^3.

[3] BEAUFORT 23 extends DEROCCO 22 who searched for the X-ray decay of axions that build up in the gravitational well of the Sun over its lifetime, the 'solar basin'. They use data from NuSTAR and SphinX telescopes and extends the previous study by accounting for the axion production via photon coalescence.

[4] BERNAL 23 use gamma-ray data from 739 blazars observed by FermiLAT and 38 blazars by Cherenkov observatories. They estimate optical depth, subtract the astrophysical component, and attribute the residual to axion two-photon decay. The quoted limit is for $m_{A^0} \simeq 25$ eV. See their Fig. 3 for the mass-dependent limits.

[5] CAPOZZI 23 use Planck CMB and Lyman-alpha observations to set limits on early energy injection by decaying dark matter axions that would affect CMB anisotropies and the reionisation history of the Universe. The quoted limit applies to $m_{A^0} = 100$ eV and the reionization model of Fauchere-Giguere. See Fig.4 for mass-dependent constraints from different reionization models.

[6] CAPOZZI 23A search for axions produced in electromagnetic showers in proton beam dumps and fixed target experiments. In this case, they reinterpret MiniBoone data. Quoted limit applies at 100 MeV but the limit does not extend to arbitrarily large couplings. See Fig. 7 for mass-dependent limits.

[7] DAVIES 23 is analogous to AJELLO 16, and use the Fermi-LAT data from three quasars (3C454.3, CTA 102, and 3C279), considering the blazer jets as the regions where the axion-photon oscillations occur. See Fig. 8 for the mass-dependent limits.

[8] DIAMOND 23 demonstrate that a window of decaying 10-MeV-mass ALP parameter space previously thought to be excluded by the lack of gamma-ray emission from the SN 1987A explosion is actually unconstrained because of the formation of a fireball that would prevent decay photons from escaping. They nevertheless re-exclude this window by considering the non-detection of the sub-MeV emission by the Pioneer Venus Orbiter. The quoted limit is at $m_{A^0} = 56$ MeV. See their Fig. 2 for mass-dependent limits.

[9] FILZINGER 23 searched for oscillations in the fine structure constant induced by dilaton-like dark matter by measuring the frequency ratio between the E3 and E2 transitions of ^{171}Yb$^+$. They assume the local dark matter density $\rho_S = 0.4$ GeV/cm^3. The quoted limit is set at $m_{S^0} \simeq 4 \times 10^{-23}$ eV. See their Fig. 4 for the limits over $m_{S^0} = 1 \times 10^{-24}$–$1 \times 10^{-17}$ eV.

[10] HOOF 23 consider axions emitted from SN1987A converting to gamma rays in Galactic magnetic fields, using temporal information of the Solar Maximum Mission data. They set a limit $G_{A\gamma\gamma} \lesssim 5 \times 10^{-12}$ for masses $m_{A^0} \lesssim 2 \times 10^{-10}$ eV. See left panel in Fig. 3 for mass-dependent limits.

[11] HOOF 23 look for gamma rays resulting from the decay of axions produced from SN1987A, using the Solar Maximum Mission data. See right panel in Fig. 3 for mass-dependent limits.

[12] JACOBSEN 23 search for the imprints of axion-photon mixing on the TeV spectra of several blazars using data from the HAWC air shower detector.

[13] LI 23H look for gamma-ray spectral irregularities induced by axion-photon oscillations from AGN VER J0521+211, using the Fermi-LAT and VERITAS data. See their Fig. 4 for mass-dependent limits.

[14] NOORDHUIS 23 places strong constraints on the axion-photon coupling over a broad mass window using the fact that the polar cap regions of pulsars can generate a population of axions, which would then convert into an observable outgoing radio flux in the presence of the neutron star's B-field. They search for this signal in 27 pulsars and set mass-dependent limits shown in their Fig. 2.

[15] PANT 23 study the effect of axion-photon oscillations on the gamma-ray spectrum from the extragalactic neutrino source, TXS 0506+056. The quoted limit is at $m_{A^0} \simeq 2.7 \times 10^{-7}$ eV. See their Fig. 2 for mass-dependent limits.

[16] SHERRILL 23 search for scalar dilaton-like dark matter via oscillations in the fundamental constants. Their most competitive constraint is on the scalar photon coupling (Fig. 6, upper panel) that affects the fine-structure constant, which they extract using an optical-to-optical clock comparison between ^{171}Yb$^+$ and ^{87}Sr. Quoted limit applies at the smallest mass in their search window for this case of 10^{-20} eV.

[17] SULAI 23 looked for ultralight axion dark matter using the "Earth as a transducer" concept over the 0.5 to 5 Hz frequency range. They situate several magnetometers at magnetically quiet places and search for spatially-correlated magnetic field patterns induced by axion dark matter interacting in the effective cavity formed between the Earth's surface and the ionosphere. See their Fig. 12 for mass-dependent limits in context. This limit extends to higher-frequencies than their previous limit using archival geomagnetic field data collected by the SuperMAG collaboration, see ARZA 22

[18] YAO 23 study an optical circular polarization in blazers induced by the axion-photon mixing. The quoted limit assumes the transverse magnetic field at the jet's emission site, with $B_T = 1$ G, and this limit inversely scales with B_T. See their Fig. 3 for the limits' dependence on B_T and electron density.

Gauge & Higgs Boson Particle Listings

Axions (A^0) and Other Very Light Bosons

[19] ZHANG 23A searched for oscillations in the fine structure constant induced by dilaton-like dark matter by measuring the frequencies of a hyperfine-structure transition in ^{87}Rb and an electronic transition in ^{164}Dy, and by comparing them with that of a quartz oscillator. They assume the local dark matter density $\rho_S \simeq 0.4$ GeV/cm^3. The quoted limit is set at $m_{S^0} \simeq 1\times10^{-17}$ eV. See their Fig. 3 for the limits over $m_{S^0} = 1\times10^{-17}$–$8.3\times10^{-13}$ eV.

[20] APRILE 22B is an update of APRILE 20 based on a similar solar axion modeling to DENT 20A and GAO 20. They exclude the XENON1T excess found in APRILE 20. The quoted limit holds for small g_{Aee}. See Fig. 6 for correlation between $G_{A\gamma\gamma}$ and g_{Aee}.

[21] ARNQUIST 22 is analogous to AVIGNONE 98, and supersedes ANASTASSOPOULOS 17 for $m_{A^0} \gtrsim 1.2$ eV.

[22] ARZA 22 search for low-mass axions as dark matter using the Earth as a transducer for axion-photon conversion. The concept works because the region between the Earth and the ionosphere forms an insulating cavity that parametrically enhances the axion signal by the radius of the Earth. The result is an oscillating and spatially correlated magnetic field induced via the interaction between axion dark matter and the geomagnetic field, which they searched for using archival magnetometer field data over 20 years compiled by the SuperMAG collaboration. Quoted limit applies for masses 3–4 $\times10^{-17}$ eV, see Fig. 1 for mass-dependent limits.

[23] BERNAL 22 explored the possibility that the excess in the cosmic optical background measured by New Horizonss Long Range Reconnaisance Imager was due to axion dark matter decaying into monoenergetic photons. See their Fig. 2 for the axion-photon coupling to explain the excess.

[24] CALORE 22 update CALORE 20 by evaluating axion fluxes from progenitors of various masses and performing a template-based analysis using 12 years of Fermi-LAT data in the energy range from 50 MeV to 500 GeV. See their Fig. 10 for mass-dependent limits.

[25] CAPUTO 22 study the effect of energy deposition by radiative decay of axions produced via the Primakoff process and photon coalescence in the supernova core, and set the limits by the radiative energy deposition $< 10^{50}$ erg and progenitor radius $= 5\times10^{13}$ cm. The quoted limit is at $m_{A^0} = 150$ MeV. See their Fig. 2 for mass-dependent limits.

[26] CASTILLO 22 update CAPUTO 19 using the polarization measurements of the Crab Pulsar by the QUIJOTE MFI instrument and 20 Galactic pulsars from the PPTA project. See their Table 1 for the assumed local axion energy density ρ_A for each pulsar and their Fig. 7 for the mass-dependent limits in the range of 3×10^{-23} eV $\leq m_{A^0} \leq 10^{-19}$ eV.

[27] DEROCCO 22 uses the NuSTAR data to search for monochromatic X-ray lines produced by the decay of solar axions trapped on bound orbits. The quoted limit applies to $m_{A^0} \simeq$ 9 keV. They also derive limits in the plane of g_{Aee} and $G_{A\gamma\gamma}$. See their Figs. 2 and 4 for mass-dependent limits.

[28] DESSERT 22A look for an axion-induced linear polarization using data from multiple magnetic white dwarf stars. See their Figs. 1 and 8 for the mass-dependent limits.

[29] ECKNER 22 set limits by using sub-PeV diffuse gamma-ray data from HAWC and Tibet ASγ by assuming that gamma rays produced simultaneously with high-energy neutrinos from extragalactic sources suggested by IceCube are converted to axions in the magnetic field at the source and reconverted to gamma rays in the Galactic magnetic field. See their Fig. 4 for mass-dependent limits.

[30] FOSTER 22 is an update of FOSTER 20 in the list of limits on relic invisible axions. They search for axion-photon transitions generated by neutron stars in the Galactic center region. They use improved population models of the Galactic center neutron stars and a Navarro-Frenk-White (NFW) model of the galactic dark matter distribution. The quoted limit applies to $m_{A^0} \simeq$ 17–25 μeV. See their Fig. 1 for mass-dependent limits.

[31] KIRITA 22 update HOMMA 21 by increasing the laser energy and developing a background discrimination method using the beam cross-section dependence of the background originated from optical elements. The quoted limits applies to $m_{A^0} = 0.18$ eV. See their Fig. 11 for mass-dependent limits.

[32] LANGHOFF 22 set limits by considering the freeze-in production of axions coupled only to photons. The quoted limit applies to $m_{A^0} = 2$ MeV for the reheating temperature equal to 5 MeV. See their Fig. 1 for mass-dependent limits.

[33] LI 22 is analogous to LI 21B, and use the spectra of the blazar FSRQ 4C+21.35 measured by MAGIC, VERITAS, and Fermi-LAT. The quoted limit applies to $m_{A^0} \simeq 8\times10^{-10}$ eV. See their Fig. 1 for mass-dependent limits.

[34] LI 22C is analogous to LI 21B, and use the spectra of the blazars Mrk 421 and PG 1553+113 measured by MAGIC and Fermi-LAT. The quoted limit applies to $m_{A^0} \simeq 1\times10^{-8}$ eV. See their Fig. 4 for mass-dependent limits.

[35] LUCENTE 22 developed a method to correctly incorporate the effects of axions decaying into photons inside the core of horizontal-branch stars. They update CARENZA 20 by evaluating axion energy transfer in the range of axion mean free path where the diffusive energy transport and free streaming approximations are not applicable. See their Fig. 1 for the limits.

[36] BASU 21 searched for birefringence induced by axion dark matter using multiple images of the polarized source in the strongly gravitationally lensed system CLASS B1152+199. They assume the axion makes up all dark matter, and used the axion density in the emitting region, $\rho_A = 20$ GeV/cm^3. Limits between 9.2×10^{-11}–7.7×10^{-8} GeV^{-1} are obtained for $m_{A^0} = 3.6\times10^{-21}$–$4.6\times10^{-18}$eV. See their Fig. 2 for mass-dependent limits.

[37] BI 21 look for the gamma-ray spectral distortions induced by axion-photon oscillations in the presence of the Galactic magnetic field, using the measurements of sub-PeV gamma-rays from the Crab Nebula by the Tibet ASγ and HAWC experiments, together with MAGIC and HEGRA gamma-ray data. See their Fig. 3 for mass-dependent limits.

[38] DOLAN 21A study the effect of axion production on the evolution of asymptotic giant branch stars, and use the white-dwarf initial-final mass relation to set the limits. See their Fig. 1 for mass-dependent limits.

[39] GUO 21 is analogous to AJELLO 16, and use the Fermi-LAT and H.E.S.S. II measurements of PG 1553+113 and PKS 2155-304. See their Fig. 6 for mass-dependent limits.

[40] HOMMA 21 look for the production of axion resonance states and their subsequent stimulated decays by combining linearly polarized creation laser pulses and circularly polarized inducing laser pulses. The quoted limit is at $m_{A^0} \simeq 0.178$ eV. See their Fig. 14 for mass-dependent limits.

[41] LI 21B is analogous to AJELLO 16, and use the spectra of the blazar Mrk 421 measured by ARGO-YBJ and Fermi-LAT. They consider ALP-photon mixing in the magnetic fields of both the blazar jet and the Galaxy. The quoted limit applies to $m_{A^0} \simeq 1\times10^{-9}$ eV. See their Fig. 5 for mass-dependent limits.

[42] LLOYD 21 is analogous to FORTIN 18, and set limits on the product of the axion couplings to photons and nucleons as $g_{ANN}\, G_{A\gamma\gamma} \lesssim 4.6\times10^{-19}$ GeV^{-1} for $m_{A^0} \lesssim 10^{-5}$ eV by using the quiescent soft gamma-ray flux upper limits in five magnetars. We use $g_{ANN} = G_{AN}\, 2m_N$ to translate their limits. See their Table II and Fig. 3 for the limits.

[43] REGIS 21 look for monochromatic photons from axion decay, using the MUSE spectroscopic data on the Leo T dwarf spheroidal galaxy. They assume that axions make up all of dark matter and use the integrated dark matter density along the line of sight determined by observations.

[44] XIAO 21 use X-ray data from Betelgeuse to look for signals from axions produced in the stellar core that were converted to X-rays by the Galactic magnetic field. See their Fig. 1 for the mass-dependent limit.

[45] ABUDINEN 20 look for the process $e^+e^- \to \gamma A^0$ ($A^0 \to \gamma\gamma$) and set upper limits of around 10^{-3} over the mass range. The quoted limit is at $m_{A^0} = 0.3$ GeV. See their Fig. 5 for mass dependent limits.

[46] BANERJEE 20A look for axions produced from high-energy bremsstrahlung photons through the Primakoff effect with the electric field of the target nuclei. They exclude $G_{A\gamma\gamma} = 2\times10^{-4}$–$5\times10^{-2}$ GeV^{-1} for $m_{A^0} < 55$ MeV. See their Fig. 5 for mass-dependent limits.

[47] BUEHLER 20 look for the γ-ray transparency due to axion-photon oscillations using high-energy photon events from 79 sources in the Second Fermi-LAT Catalog of High-Energy Sources. The quoted limit is for the intergalactic magnetic field strength and coherence length of $B = 1$ nG and $s = 1$ Mpc. See their Figs. 4 and 5 for mass-dependent limits and for different magnetic-field parameters.

[48] CALORE 20 use the isotropic diffuse γ-ray background measured by the Fermi-LAT to constrain the γ-ray flux converted in the Galactic magnetic field from axions produced from past core-collapse supernovae. They also derive a limit on a heavier axion with $m_{A^0} \gtrsim$ keV decaying into two photons of $G_{A\gamma\gamma} \lesssim 5\times10^{-11}$ GeV^{-1} for $m_{A^0} = 5$ keV. See their Figs. 5 and 7 for the limits as well as limits in the presence of axion-nucleon couplings.

[49] CARENZA 20 extend the globular cluster bound of AYALA 14 to heavier masses ($m_{A^0} \leq$ a few 100 keV) by taking account of the coalescence process $\gamma + \gamma \to A^0$ as well as the decay of the ALP inside the stellar core. See their Fig.4 for mass-dependent limits.

[50] DENT 20A is analogous to GAO 20. The quoted limit is from their arXiv:2006.15118v3 (v2 is their published version), using the relativistic Hartree-Fock form factor. The limit is up to two times weaker than the published one. See Fig. 4 in their arXiv version 3 for the correlation between $G_{A\gamma\gamma}$ and g_{Aee} corresponding to the excess reported in APRILE 20.

[51] DEPTA 20 correct the underestimated D abundance in MILLEA 15, and derive robust cosmological bounds by allowing the reheating temperature, $N_{\rm eff}$, and neutrino chemical potential to vary. See their Fig. 6 for mass-dependent limits.

[52] DESSERT 20A use the NuSTAR data of the Quintuplet and Westerlund 1 super star clusters to look for X-rays converted in the Galactic magnetic field from the axions produced in stellar cores. See their Fig. 3 for the mass-dependent limits.

[53] ESTEBAN 20 show that the two anomalous ANITA events can be explained by the reflected radio pulses that are resonantly produced in the ionosphere via axion-photon conversion for $m_{A^0} \lesssim 1\times10^{-7}$ eV , if an axion clump passes the Earth about once a month. See their Fig.5 for the region consistent with this interpretation for different values of the axion density inside the clumps.

[54] GAO 20 correct the limit of APRILE 20 by including inverse Primakoff scattering in the XENON1T detector. The quoted limit is from their arXiv:2006.14598v4 (v3 is their published version), taking account of the atomic form factor of Xe as pointed out in ABE 20J. The limit is weaker by a factor of 1.5–2 than the published one. See Fig. 3 in their arXiv version 4 for correlation between $G_{A\gamma\gamma}$ and g_{Aee} corresponding to the excess reported in APRILE 20.

[55] KOROCHKIN 20 assume the axion makes up all dark matter, and look for a dip in the observed gamma-ray spectrum of the blazer 1ES 1218+304 by Fermi/LAT and VERITAS due to the extragalactic background light produced by the axion decay. Their analysis favors nonzero axion-induced absorption with $G_{A\gamma\gamma} = 3\times10^{-11}$–$2\times10^{-10}$ GeV^{-1} over a range of $m_{A^0} = 2$–18 eV. See their Fig. 1 for mass-dependent limits between $0.25 < m_{A^0} < 25$ eV.

[56] LUCENTE 20A study the SN 1987A energy-loss argument on the axion-like particle production. In addition to the Primakoff process, they take account of photon coalescence as well as gravitational trapping that become relevant at $m_{A^0} > 100$ MeV. See their Fig. 12 for the mass-dependent limit.

[57] MEYER 20 look for prompt γ-rays converted in the Galactic magnetic fields from axions produced via the Primakoff process in a sample of 20 extragalactic core-collapse supernovae. The limits assume a progenitor mass of 10 times the solar mass and certain models for the optical emission and the galactic magnetic field. See their Figs. 2 and 6 in the erratum for mass- and model-dependent limits.

[58] YAMAMOTO 20 look for X-ray photons converted by the Earth's magnetic field from the axions produced by the two-body decay of dark matter, and set the limits by using the Suzaku data. The quoted limit is for the monochromatic X-ray line from the galactic dark matter with lifetime $\tau = 4.32\times10^{17}$ sec. They also derive limits on the continuum spectrum from the extragalactic component. See their Fig. 7 for the limits.

[59] ALONI 19 used the data collected by the PRIMEX experiment to derive a limit based on a data-driven method. See their Fig. 2 for mass-dependent limits.

[60] CAPUTO 19 look for an oscillating variation of the polarization angle of the pulsar J0437-4715, where they assume the local axion energy density $\rho_A = 0.3$ GeV/cm^3. See their Fig. 2 for mass-dependent limits for 5×10^{-24} eV $\leq m_{A^0} \leq 2\times10^{-19}$ eV.

[61] FEDDERKE 19 look for a uniform reduction of the CMB polarization at large scales, which is induced by the oscillating axion background during CMB decoupling. The quoted limit is based on the assumption that axions make up all of the dark matter. See their Fig. 3 for mass-dependent limits for $m_{A^0} = 10^{-22}$–10^{-19} eV.

[62] IVANOV 19 look for the axion-induced periodic changes in the polarization angle of parsec-scale jets in active galactic nuclei observed by the MOJAVE program, where they use the axion energy density $\rho_A = 20$ GeV/cm^3. See their Fig. 6 for mass-dependent limits for 5×10^{-23} eV $\leq m_{A^0} \leq 1.2\times10^{-21}$ eV.

[63] LIANG 19 look for spectral irregularities in the spectrum of 10 bright H.E.S.S. sources in the Galactic plane, assuming photon-ALP mixing in the Galactic magnetic fields. See their Fig. 2 for mass-dependent limits with different Galactic magnetic field models.

[64] FORTIN 18 studied the conversion of axion-like particles produced in the core of a magnetar to hard X-rays in the magnetosphere. See their Fig. 5 for mass-dependent limits with different values of the magnetar core temperature.

[65] JAECKEL 18 study axions produced through the Primakoff process from SN 1987A, which subsequently decay into photon pairs. See their Fig. 1 for the mass-dependent limits in the range of $m_{A^0} = 0.01$–100 MeV.

[66] YAMAJI 18 search for axions with an x-ray LSW at Spring-8, using the Laue-case conversion in a silicon crystal. They also obtain $G_{A\gamma\gamma} < 4.2\times10^{-3}$ GeV^{-1} for $m_{A^0} <$ 10 eV. See their Fig. 5 for mass-dependent limits.

[67] ZHANG 18 look for spectral irregularities in the spectrum of PKS 2155-304 measured by Fermi LAT, assuming photon-ALP mixing in the intercluster and Galactic magnetic fields. See their Figs. 2 and 3 for mass-dependent limits with different values of the intercluster magnetic field parameters.

[68] ADE 17 look for cosmic birefringence from axion-like particles using CMB polarization data taken by the BICEP2 and Keck Array experiments. They set a limit $G_{A\gamma\gamma}H_I < 7.2\times10^{-2}$ at 95 %CL for $m_{A^0} < 10^{-28}$ eV, where H_I is the Hubble parameter during inflation.

[69] ANASTASSOPOULOS 17 looked for solar axions by the CAST axion helioscope in the vacuum phase, and supersedes ANDRIAMONJE 07.

[70] DOLAN 17 update existing limits on $G_{A\gamma\gamma}$ for axion-like particles. The limits from the proton beam dump experiments in their Fig. 2 contained an error, and the corrected version is shown in Fig. 1 of DOLAN 21.

[71] INADA 17 search for axions with an x-ray LSW at Spring-8. See their Fig. 4 for mass-dependent limits.

[72] KOHRI 17 attributed to axion-photon oscillations the excess of cosmic infrared background observed by the CIBER experiment. See their Fig. 5 for the region preferred by their scenario.

[73] MARSH 17 is similar to WOUTERS 13, using Chandra observations of M87. See their Fig. 6 for mass-dependent limits.

[74] TIWARI 17 use observed limits of the cosmic distance-duality relation to constrain the photon-ALP mixing based on 3D simulations of the magnetic field configuration. The quoted value is for the averaged magnetic field of 1nG with a coherent length of 1 Mpc. See their Fig. 5 for mass-dependent limits.

[75] AJELLO 16 look for irregularities in the energy spectrum of the NGC1275 measured by Fermi LAT, assuming photon-ALP mixing in the intra-cluster and Galactic magnetic fields. See their Fig. 2 for mass-dependent limits.

[76] DELLA-VALLE 16 look for the birefringence induced by axion-like particles. See their Fig. 14 for mass-dependent limits.

[77] DELLA-VALLE 16 look for the dichroism induced by axion-like particles. See their Fig. 14 for mass-dependent limits.

[78] JAECKEL 16 use the LEP data of $Z \to 2\gamma$ and $Z \to 3\gamma$ to constrain the ALP production via $e^+e^- \to Z \to A^0\gamma\,(A^0 \to \gamma\gamma)$, assuming the ALP coupling with two hypercharge bosons. See their Fig. 4 for mass-dependent limits.

[79] LEEFER 16 derived limits by using radio-frequency spectroscopy of dysprosium and atomic clock measurements. See their Fig. 1 for mass-dependent limits as well as limits on Yukawa-type couplings of the scalar to the electron and nucleons.

[80] ANASTASSOPOULOS 15 search for solar chameleons with CAST and derived limits on the chameleon coupling to photons and matter. See their Fig. 12 for the exclusion region.

[81] ARIK 15 is analogous to ARIK 09, and search for solar axions for m_{A^0} around 0.2 and 0.4 eV. See their Figs. 1 and 3 for the mass-dependent limits.

[82] Based on OSQAR photon regeneration experiment. See their Fig. 6 for mass-dependent limits on scalar and pseudoscalar bosons.

[83] BRAX 15 derived limits on conformal and disformal couplings of a scalar to photons by searching for a chaotic absorption pattern in the X-ray and UV bands of the Hydra A galaxy cluster and a BL lac object, respectively. See their Fig. 8.

[84] HASEBE 15 look for an axion via a four-wave mixing process at quasi-parallel colliding laser beams. They also derived limits on a scalar coupling to photons $G_{S\gamma\gamma} < 2.62\times10^{-4}$ GeV^{-1} at $m_{S^0} = 0.15$ eV. See their Figs. 11 and 12 for mass-dependent limits.

[85] MILLEA 15 is similar to CADAMURO 12, including the Planck data and the latest inferences of primordial deuterium abundance. See their Fig. 3 for mass-dependent limits.

[86] VANTILBURG 15 look for harmonic variations in the dyprosium transition frequency data, induced by coherent oscillations of the fine-structure constant due to dilaton-like dark matter, and set the limits, $G_{S\gamma\gamma} < 6\times10^{-27}$ GeV^{-1} at $m_{S^0} = 6\times10^{-23}$ eV. See their Fig. 4 for mass-dependent limits between $1\times10^{-24} < m_{S^0} < 1\times10^{-15}$ eV.

[87] VINYOLES 15 performed a global fit analysis based on helioseismology and solar neutrino observations. See their Fig. 9.

[88] ARIK 14 is similar to ARIK 11. See their Fig. 2 for mass-dependent limits.

[89] AYALA 14 derived the limit from the helium-burning lifetime of horizontal-branch stars based on number counts in globular clusters.

[90] DELLA-VALLE 14 use the new PVLAS apparatus to set a limit on vacuum magnetic birefringence induced by axion-like particles. See their Fig. 6 for the mass-dependent limits.

[91] EJLLI 14 set limits on a product of primordial magnetic field and the axion mass using CMB distortion induced by resonant axion production from CMB photons. See their Fig. 1 for limits applying specifically to the DFSZ and KSVZ axion models.

[92] PUGNAT 14 is analogous to EHRET 10. See their Fig. 5 for mass-dependent limits on scalar and pseudoscalar bosons.

[93] REESMAN 14 derive limits by requiring effects of axion-photon interconversion on gamma-ray spectra from distant blazars to be no larger than errors in the best-fit optical depth based on a certain extragalactic background light model. See their Fig. 5 for mass-dependent limits.

[94] ABRAMOWSKI 13A look for irregularities in the energy spectrum of the BL Lac object PKS 2155–304 measured by H.E.S.S. The limits depend on assumed magnetic field around the source. See their Fig. 7 for mass-dependent limits.

[95] ARMENGAUD 13 is analogous to AVIGNONE 98. See Fig. 6 for the limit.

[96] BETZ 13 performed a microwave-based light shining through the wall experiment. See their Fig. 13 for mass-dependent limits.

[97] FRIEDLAND 13 derived the limit by considering blue-loop suppression of the evolution of red giants with 7–12 solar masses.

[98] MEYER 13 attributed to axion-photon oscillations the observed excess of very high-energy γ-rays with respect to predictions based on extragalactic background light models. See their Fig.4 for mass-dependent lower limits for various magnetic field configurations.

[99] WOUTERS 13 look for irregularities in the X-ray spectrum of the Hydra cluster observed by Chandra. See their Fig. 4 for mass-dependent limits.

[100] CADAMURO 12 derived cosmological limits on $G_{A\gamma\gamma}$ for axion-like particles. See their Fig. 1 for mass-dependent limits.

[101] PAYEZ 12 derive limits from polarization measurements of quasar light (see their Fig. 3). The limits depend on assumed magnetic field strength in galaxy clusters. The limits depend on assumed magnetic field and electron density in the local galaxy supercluster.

[102] ARIK 11 search for solar axions using ^{3}He buffer gas in CAST, continuing from the ^{4}He version of ARIK 09. See Fig. 2 for the exact mass-dependent limits.

[103] ALPS is a photon regeneration experiment. See their Fig. 4 for mass-dependent limits on scalar and pseudoscalar bosons.

[104] AHMED 09A is analogous to AVIGNONE 98.

[105] ARIK 09 is the ^{4}He filling version of the CAST axion helioscope in analogy to INOUE 02 and INOUE 08. See their Fig. 7 for mass-dependent limits.

[106] CHOU 09 use the GammeV apparatus in the afterglow mode to search for chameleons, (pseudo)scalar bosons with a mass depending on the environment. For pseudoscalars they exclude at 3σ the range 2.6×10^{-7} GeV$^{-1} < G_{A\gamma\gamma} < 4.2\times10^{-6}$ GeV^{-1} for vacuum m_{A^0} roughly below 6 meV for density scaling index exceeding 0.8.

[107] GONDOLO 09 use the all-flavor measured solar neutrino flux to constrain solar interior temperature and thus energy losses.

[108] LIPSS photon regeneration experiment, assuming scalar particle S^0. See Fig. 4 for mass-dependent limits.

[109] CHOU 08 perform a variable-baseline photon regeneration experiment. See their Fig. 3 for mass-dependent limits. Excludes the PVLAS result of ZAVATTINI 06.

[110] FOUCHE 08 is an update of ROBILLIARD 07. See their Fig. 12 for mass-dependent limits.

[111] INOUE 08 is an extension of INOUE 02 to larger axion masses, using the Tokyo axion helioscope. See their Fig. 4 for mass-dependent limits.

[112] ZAVATTINI 08 is an upgrade of ZAVATTINI 06, see their Fig. 8 for mass-dependent limits. They now exclude the parameter range where ZAVATTINI 06 had seen a positive signature.

[113] ANDRIAMONJE 07 looked for Primakoff conversion of solar axions in 9T superconducting magnet into X-rays. Supersedes ZIOUTAS 05.

[114] ROBILLIARD 07 perform a photon regeneration experiment with a pulsed laser and pulsed magnetic field. See their Fig. 4 for mass-dependent limits. Excludes the PVLAS result of ZAVATTINI 06 with a CL exceeding 99.9%.

[115] ZAVATTINI 06 propagate a laser beam in a magnetic field and observe dichroism and birefringence effects that could be attributed to an axion-like particle. This result is now excluded by ROBILLIARD 07, ZAVATTINI 08, and CHOU 08.

[116] INOUE 02 looked for Primakoff conversion of solar axions in 4T superconducting magnet into X ray.

[117] MORALES 02B looked for the coherent conversion of solar axions to photons via the Primakoff effect in Germanium detector.

[118] BERNABEI 01B looked for Primakoff coherent conversion of solar axions into photons via Bragg scattering in NaI crystal in DAMA dark matter detector.

[119] ASTIER 00B looked for production of axions from the interaction of high-energy photons with the horn magnetic field and their subsequent re-conversion to photons via the interaction with the NOMAD dipole magnetic field.

[120] MASSO 00 studied limits on axion-proton coupling using the induced axion-photon coupling through the proton loop and CAMERON 93 bound on the axion-photon coupling using optical rotation. They obtained the bound $g_p^2/4\pi < 1.7\times10^{-9}$ for the coupling $g_p\overline{p}\gamma_5 p\phi_A$.

[121] AVIGNONE 98 result is based on the coherent conversion of solar axions to photons via the Primakoff effect in a single crystal germanium detector.

[122] Based on the conversion of solar axions to X-rays in a strong laboratory magnetic field.

[123] Experiment based on proposal by MAIANI 86.

[124] Experiment based on proposal by VANBIBBER 87.

[125] LAZARUS 92 experiment is based on proposal found in VANBIBBER 89.

[126] RUOSO 92 experiment is based on the proposal by VANBIBBER 87.

[127] SEMERTZIDIS 90 experiment is based on the proposal of MAIANI 86. The limit is obtained by taking the noise amplitude as the upper limit. Limits extend to $m_{A^0} = 4\times10^{-3}$ where $G_{A\gamma\gamma} < 1\times10^{-4}$ GeV^{-1}.

Limit on Invisible A^0 (Axion) Electron Coupling

The limit is for $g_{Aee}\,\phi_A\,\overline{e}(i\,\gamma_5)e$, or equivalently, the dipole-dipole potential $-\frac{g^2_{Aee}}{16\pi m^2_e}\,((\boldsymbol{\sigma}_1\cdot\boldsymbol{\sigma}_2) - 3(\boldsymbol{\sigma}_1\cdot\boldsymbol{n})\,(\boldsymbol{\sigma}_2\cdot\boldsymbol{n}))/r^3$ where $\boldsymbol{n}=\boldsymbol{r}/r$ and the sign of the potential was corrected based on DAIDO 17.

[1] AALBERS 23A look for solar axions from the ABC processes. See their Fig. 6 for the limits.

[2] AALBERS 23A look for absorption of axion dark matter. The quoted limit is for $m_{A^0} \simeq 1.4$ keV. The local density $\rho_A = 0.3$ GeV/cm^3 is assumed. See their Fig. 7 for mass-dependent limits.

[3] ADHIKARI 23 is an update of ADHIKARI 19B.

[4] ADHIKARI 23A look for absorption and Compton-like processes of axion dark matter. The quoted limit is for $m_{A^0} \simeq 37$ keV. See their Fig. 4 for mass-dependent limits.

[5] AGNES 23A look for absorption of axion dark matter. The quoted limit is for $m_{A^0} \simeq 0.25$ keV. The local density $\rho_A = 0.3$ GeV/cm^3 is assumed. See their Fig. 2 for mass-dependent limits.

[6] APRILE 23B look for an absorption signal of axions within $\pm$500 seconds of the GW signals, including the neutron star merger GW170817. They set a 90% CL upper limit on the product of coincident fluence and cross section of axions to be less than 10^{-29} cm^2/cm^2 in the recoil energy range of 5.5–210 keV$_{ee}$.

[7] CAPOZZI 23A search for axions produced in electromagnetic showers in proton beam dumps and fixed target experiments. In this case, they reinterpret MiniBoone data. Quoted limit applies at 1 MeV. See Fig. 8 for mass-dependent limits.

[8] WADEKAR 23 use the Leo T dwarf galaxy's interstellar medium to derive limits, requiring the heating rate from axion dark matter absorption into hydrogen atoms and two-photon decay to be less than the astrophysical cooling rate. See Fig. 2 for limits over $m_{A^0} =$ 1–100 keV, which loosen for lighter masses.

[9] APRILE 22 extend APRILE 19D to lower masses by removing the background of ionization signals correlated with high-energy events. The quoted limit applies to $m_{A^0} = 0.1$ keV. See their Fig. 15 for mass-dependent limits.

[10] APRILE 22B is an update of APRILE 20, and set the limit, $g_{Aee} \lesssim 9 \times 10^{-15}$–$3 \times 10^{-13}$. The quoted limit applies to $m_{A^0} = 2$ keV. They exclude the XENON1T excess found in APRILE 20. See their Fig. 6 for mass-dependent limits.

[11] APRILE 22B is an update of APRILE 20. They exclude the XENON1T excess found in APRILE 20. The quoted limit holds for small $G_{A\gamma\gamma}$. See their Fig. 6 for correlation between g_{Aee} and $G_{A\gamma\gamma}$.

[12] DESSERT 22 is an update of DESSERT 19. They used the Chandra observation of the magnetic white dwarf RE J0317-853 to look for converted X-rays in the magnetosphere from axions produced in the core through electron bremsstrahlung. They obtained the limit, $g_{Aee} \cdot G_{A\gamma\gamma} < 1.3 \times 10^{-25}$ GeV^{-1} at 95% CL for $m_{A^0} \lesssim 10^{-5}$ eV. See their Fig. 1 for mass-dependent limits.

[13] IKEDA 22 look for magnons excited by dark matter axions, using data taken with a hybrid quantum system consisting of a superconducting qubit and a spherical ferrimagnetic crystal. The quoted limit assumes the local dark matter density $\rho_A = 0.45$ GeV/cm^3 and the velocity $v = 220$ km/sec. See their Fig. 4 for the limits.

[14] LANGHOFF 22 set limits by considering the freeze-in production of axions coupled to electrons without anomalous coupling to photons. The quoted limit applies to $m_{A^0} = 15$ MeV for the reheating temperature equal to 5 MeV. See their Fig. 2 for mass-dependent limits.

[15] WANG 22C use the spin-amplifier based on hyperpolarized ^{129}Xe to set limits on the product of the axion couplings to electrons and nucleons as $g_{Aee}\, g_{Ann} < 4 \times 10^2$ (95 % CL) at $m_{A^0} = 0.1$ meV. Here g_{Ann} is the dimensionless axion-neutron coupling. See their Fig. 4 for the mass-dependent limits.

[16] XIAO 22 extend XIAO 21 in the list of photon coupling limits by including the production of axions from Compton and bremsstrahlung processes, and set limits on the product of the axion couplings to electrons and photons as $G_{A\gamma\gamma}\, g_{Aee} < 0.4$–$2.8 \times 10^{-24}$ GeV^{-1} (95 % CL) for $m_{A^0} < 3.5 \times 10^{-11}$eV. See their Fig. 5 for the limits. They are comparable to those of DESSERT 19 and more restrictive than the CAST bounds of BARTH 13.

[17] CALORE 21 consider the production of axions from Galactic and extragalactic SNe via nucleon-nucleon bremsstrahlung and their subsequent decay into electron-positron pairs, and exclude the range of $g_{Aee} \simeq 10^{-19}$–10^{-11} at $g_{App} = 10^{-9}$ for $m_{A^0} =$ 3–30 MeV. See their Fig. 7 for the limits.

[18] LUCENTE 21 study the axion production in a supernova via electron-proton bremsstrahlung and electron-positron fusion, and exclude the range of $g_{Aee} \simeq 10^{-10}$–10^{-8} for $m_{A^0} =$ 1–160 MeV. The quoted limit is at $m_{A^0} = 120$ MeV. See their Fig. 12 for the mass-dependent limits.

[19] AGOSTINI 20 is analogous to AHMED 09A. The quoted limit applies to $m_{A^0} = 150$ keV. Their limits in their Fig. 3 were later found to be incorrect due to an error of their Eqs. (1) and (2). See Fig. 3 in AGOSTINI 22A for the corrected limits.

[20] AMARAL 20 use a second-generation SuperCDMS high-voltage eV-resolution detector to set limits on dark-matter axion absorption. The quoted limit is for $m_{A^0} \simeq 17$ eV. The local density $\rho_A = 0.3$ GeV/cm^3 is assumed. See their Fig. 3 for mass-dependent limits.

[21] APRILE 20 is an update of APRILE 17B where they look for an absorption signal of axion dark matter. They obtained the limit, $g_{Aee} \lesssim 2 \times 10^{-14}$–$1 \times 10^{-12}$ at 90%CL for $m_{A^0} =$ 1–200 keV. They also found an excess over known backgrounds, which favors the mass $m_{A^0} = 2.3 \pm 0.2$ keV with a 3 σ significance. See their Fig. 10 for mass-dependent limits.

[22] APRILE 20 look for solar axions from the ABC interactions, the Primakoff conversion, and the 14.4 keV M1 transition of ^{57}Fe, and set limits on g_{Aee}, $G_{A\gamma\gamma}$, g_{ANN}, and their products. An excess is observed at low energies between 2 and 3 keV. See their Fig.8 for correlation between the couplings. The quoted limit applies to the case of vanishing $G_{A\gamma\gamma}$ and g_{ANN}.

[23] ARALIS 20 is analogous to AHMED 09A. The quoted limit applies to $m_{A^0} = 0.3$ keV. The limits at masses above 3 keV in their Fig. 9 was later found to be incorrect due to an error in their analysis. See Fig. 2 in ARALIS 21 for the corrected limits.

[24] CAPOZZI 20 obtains a limit on the axion-electron coupling from the brightness of the tip of the red-giant branch in ω Centauri. A similar limit of $< 1.6 \times 10^{-13}$ is obtained in NGC 4258.

[25] CRESCINI 20 is an update of CRESCINI 18. They assume a local axion dark matter density, $\rho_A = 0.3$ GeV/cm^3. See their Fig.4 for the limits.

[26] GHOSH 20A study thermal production of axion via coupling to leptons in the early universe and estimate its contribution to $\Delta N_{\rm eff}$. The quoted limit is for $\Delta N_{\rm eff} < 0.5$. See their Fig. 7 for their mass-dependent limits.

[27] STRANIERO 20 is analogous to CAPOZZI 20, with 22 galactic globular clusters used to derive the limit.

[28] WANG 20A is an update of LIU 17A. See their Fig. 9.

[29] WANG 20A is an update of LIU 17A. They assume a local axion dark matter density, $\rho_A = 0.3$ GeV/cm^3. See their Fig. 10 for limits between $0.185 < m_{A^0} < 10$ keV.

[30] ADHIKARI 19B is analogous to LIU 17A.

[31] APRILE 19D is analogous to APRILE 17B, but they use only ionization signals. The quoted limit applies to $m_{A^0} = 0.7$ keV. See their Fig. 5(e) for mass-dependent limits.

[32] DESSERT 19 used the Suzaku observations of a magnetic white dwarf (RE J0317-853) to look for X-ray signatures converted from axions in the surrounding magnetic fields. They obtained the limit, $g_{Aee} \cdot G_{A\gamma\gamma} < 1.6 \times 10^{-24}$ GeV^{-1} at 95%CL for $m_{A^0} \lesssim 10^{-5}$ eV. See their Fig. 2 for mass-dependent limits.

[33] TERRANO 19 look for the axion-induced oscillating magnetic field acting on the electron spin, using data taken with a rotating torsion pendulum containing polarized electrons.

The quoted limit applies to $m_{A^0} = 10^{-23}$–10^{-18} eV and assumes a local axion dark matter density, $\rho_A = 0.45$ GeV/cm^3. See their Fig. 5 for mass-dependent limits.

[34] ABE 18F is an update of ABE 14F. The quoted limit applies to $m_{A^0} = 60$ keV. See their Fig. 5 for mass-dependent limits.

[35] ARMENGAUD 18 is analogous to LIU 17A.

[36] ARMENGAUD 18 is analogous to AHMED 09A. See the left panel of Fig. 5 for mass-dependent limits.

[37] CRESCINI 18 look for collective excitations of the electron spins caused by dark matter axions. The quoted limit assumes the local dark matter density, $\rho_A = 0.45$ GeV/cm^3.

[38] FICEK 18 use the measurements of the hyperfine structure of antiprotonic helium to constrain a dipole-dipole potential between electron and antiproton. See their Fig. 3 for limits on various spin- and velocity-dependent potentials.

[39] ABGRALL 17 is analogous to AHMED 09A using the MAJORANA DEMONSTRATOR. See their Fig. 2 for limits between 6 keV $< m_{A^0} <$ 97 keV.

[40] AKERIB 17B is analogous to LIU 17A.

[41] AKERIB 17B is analogous to AHMED 09A. See their Fig. 7 for mass-dependent limits.

[42] APRILE 17B is analogous to AHMED 09A. They found a bug in their code and needed to correct the limits in Fig. 7 of APRILE 14B. See their Fig. 1 for the corrected limits between 1 keV $< m_{A^0} <$ 40 keV.

[43] FICEK 17 look for spin-dependent interactions between electrons by comparing precision spectroscopic measurements in ^{4}He with theoretical calculations. See their Fig. 1 for limits up to $m_{A^0} = 10$ keV.

[44] FU 17A is analogous to LIU 17A. See their Fig. 3 for mass-dependent limits.

[45] FU 17A is analogous to AHMED 09A. See their Fig. 4 for mass-dependent limits.

[46] LIU 17A is analogous to AHMED 09A. See their Fig. 9 for limits between 0.25 keV $< m_{A^0} <$ 20 keV.

[47] LIU 17A look for solar axions produced from Compton, bremsstrahlung, atomic-recombination and deexcitation channels, and set a limit for $m_{A^0} < 1$ keV.

[48] LUO 17 use a recent measurement of the dipole-dipole interaction between two iron atoms at the nanometer scale and set a limit for $m_{A^0} < 1$ keV. See their Fig. 3 for mass-dependent limits.

[49] BATTICH 16 is analogous to CORSICO 16 and used the pulsating DB white dwarf PG 1351+489.

[50] CORSICO 16 studied the cooling rate of the pulsating DA white dwarf L19-2 based on an asteroseismic model.

[51] YOON 16 look for solar axions with the axio-electric effect in CsI(Tl) crystals and set a limit for $m_{A^0} < 1$ keV.

[52] TERRANO 15 used a torsion pendulum and rotating attractor with 20-pole electron-spin distributions. See their Fig. 4 for a mass-dependent limit up to $m_{A^0} = 500$ μeV.

[53] ABE 14F set limits on the axioelectric effect in the XMASS detector assuming the pseudoscalar constitutes all the local dark matter. See their Fig. 3 for limits between m_{A^0} = 40–120 keV.

[54] APRILE 14B look for solar axions using the XENON100 detector.

[55] APRILE 14B is analogous to AHMED 09A. Their Fig. 7 was later found to be incorrect due to a bug in their code. See Fig. 1 in APRILE 17B for the corrected limits.

[56] DERBIN 14 is an update of DERBIN 13 with a BGO scintillating bolometer. See their Fig. 3 for mass-dependent limits.

[57] MILLER-BERTOLAMI 14 studied the impact of axion emission on white dwarf cooling in a self-consistent way.

[58] ABE 13D is analogous to DERBIN 12, using the XMASS detector.

[59] ARMENGAUD 13 is similar to AALSETH 11. See their Fig. 10 for limits between 3 keV $< m_{A^0} <$ 100 keV.

[60] ARMENGAUD 13 is similar to DERBIN 12, and take account of axio-recombination and axio-deexcitation effects. See their Fig. 12 for mass-dependent limits.

[61] BARTH 13 search for solar axions produced by axion-electron coupling, and obtained the limit, $g_{Aee} \cdot G_{A\gamma\gamma} < 8.1 \times 10^{-23}$ GeV^{-1} at 95%CL.

[62] DERBIN 13 looked for 5.5 MeV solar axions produced in $pd \to {}^3\mathrm{He}\, A^0$ in a BGO detector through the axioelectric effect. See their Fig. 4 for mass-dependent limits.

[63] HECKEL 13 studied the influence of 2 or 4 stationary sources each containing 6.0×10^{24} polarized electrons, on a rotating torsion pendulum containing 9.8×10^{24} polarized electrons. See their Fig. 4 for mass-dependent limits.

[64] VIAUX 13A constrain axion emission using the observed brightness of the tip of the red-giant branch in the globular cluster M5.

[65] CORSICO 12 attributed the excessive cooling rate of the pulsating white dwarf R548 to emission of axions with $g_{Aee} \simeq 4.8 \times 10^{-13}$.

[66] DERBIN 12 look for solar axions with the axio-electric effect in a Si(Li) detector. The solar production is based on Compton and bremsstrahlung processes.

[67] AALSETH 11 is analogous to AHMED 09A. See their Fig. 4 for mass-dependent limits.

[68] AHMED 09A assume keV-mass pseudoscalars are the local dark matter and constrain the axio-electric effect in the CDMS detector. See their Fig. 5 for mass-dependent limits.

[69] DAVOUDIASL 09 use geophysical constraints on Earth cooling by axion emission.

[70] These experiments measured induced magnetization of a bulk material by the spin-dependent potential generated from other bulk material with aligned electron spins, where the magnetic field is shielded with superconductor. The sign of the limit set by CHUI 93 is opposite to that of the axion-mediated dipole-dipole potential.

[71] These experiments used a torsion pendulum to measure the potential between two bulk matter objects where the spins are polarized but without a net magnetic field in either of them. The limits reflect the corrected sign of the dipole-dipole potential.

[72] WINELAND 91 looked for an effect of bulk matter with aligned electron spins on atomic hyperfine splitting using nuclear magnetic resonance.

Invisible A^0 (Axion) Limits from Nucleon Coupling

Limits are for the axion mass in eV.

[1] LELLA 24 update constraints on the axion-proton coupling from supernova 1987A based on the SN cooling argument (including a treatment of the trapping regime) as well as the non-observation of any coincident axion-induced events in the Kamiokande II neutrino detector. They exclude QCD axion models above 0.01 eV, and axion-like particles in a window that extends up to 300 MeV. See their Fig. 3 for mass-dependent limits.

[2] KARANTH 23 utilized an in-plane polarized deuteron beam in a storage ring to constrain the axion-induced oscillating EDM of the deuteron for $m_{A^0} = 0.496$–0.502 neV. Assuming axions account for all dark matter with $\rho_A \simeq 0.55$ GeV/cm^3, they derived constraints on axion couplings to the deuteron EDM operator, gluons, and the deuteron spin. For detailed limits, see their Figs. 19–21.

[3] LEE 23 analyzed data from a K–^{3}He comagnetometer, accounting for stochastic effects, to limit the axion-neutron coupling $g_{Ann} < 2.4 \times 10^{-10}$ GeV^{-1} at 95% CL for m_{A^0} = 0.4–4 feV. They assumed axions form all dark matter with a density of 0.3 GeV/cm^3. See their Fig. 5 for the limits.

[4] BUSCHMANN 22 studied the axion emission from five neutron stars with ages $\sim 10^5$–10^6 years, comparing the simulation with axions to age and luminosity measurements. The mass bound assumes the KSVZ axion model with $C_p = -0.47$ and $C_n = -0.02$. See their Fig. 3 for the limits on the DFSZ axion model.

[5] GAVRILYUK 22 look for solar axions from the ABC interactions with the experimental setup similar to GAVRILYUK 15. The mass bound assumes the KSVZ axion model, $S = 0.5$, and $m_u/m_d = 0.56$.

[6] SCHULTHESS 22 look for a time-oscillating neutron EDM caused by the coupling between axion dark matter and gluons, using a Ramsey-type apparatus for a cold neutron beam. See their Fig. 4 for limits in the range of $m_{A^0} = 10^{-19}$–4×10^{-12} eV.

[7] AYBAS 21 limits the axion couplings to the nucleon EDM and the nucleons as $g_{AN\gamma} < 9.5 \times 10^{-4}$ GeV^{-2} and $g_{ANN}/2m_N < 0.28$ GeV^{-1} (95 % CL) for $m_{A^0} = 162$–166 neV, based on a measurement of ^{207}Pb solid-state NMR in a polarized ferroelecrtric crystal. Here m_N is the nucleon mass and g_{ANN} is the dimensionless axion-nucleon coupling. They assume that axions make up all the dark matter with $\rho_A \simeq 0.46$ GeV/cm^3. See their Fig. 3 for the limits.

[8] BHUSAL 21 looked for 5.5 MeV solar axions produced by $pd \to {}^3\mathrm{He}\, A^0$ through the axion-induced dissociation of deuterons by using SNO data, and set a limit on the isovector axion-nucleon coupling, $|g^3_{aN}| < 2 \times 10^{-5}$ GeV^{-1}, which is equivalent to $|g_{Ann} - g_{App}| < 4 \times 10^{-5}$ in terms of the dimensionless axion-nucleon couplings.

[9] JIANG 21 use the spin-amplifier based on hyperpolarized ^{129}Xe gas to set limits on the axion couplings to nucleons as $g_{ANN}/2m_N < 3.2 \times 10^{-9}$ GeV^{-1} (95 % CL) at $m_{A^0} = 52.94$ feV, and comparable limits in the mass range of 8.3–744 feV. Here m_N is the nucleon mass and g_{ANN} is the dimensionless axion-nucleon coupling. They assume that axions make up all the dark matter with $\rho_A \simeq 0.4$ GeV/cm^3. See their Fig. 4b for the limits.

[10] ROUSSY 21 look for a time-oscillating EDM of molecular ions HfF$^+$ induced by axion dark matter couplings to gluons. See their Fig. 3 for limits in the range of $m_{A^0} = 10^{-22}$–10^{-15} eV.

Gauge & Higgs Boson Particle Listings

Axions (A^0) and Other Very Light Bosons

[11] ZHANG 21B use the gravitational waves from the binary neutron star inspiral GW170817 to look for a type of axion whose mass is suppressed due to cancellation with additional contributions. They exclude $1.6\times10^{16} < f_A < 10^{18}$ GeV at 3 σ for $m_{A^0} \lesssim 10^{-13}$ eV. See their Fig. 1 for mass-dependent limits.

[12] ABDELHAMEED 20 look for the resonant excitation of ^{169}Tm (8.41 keV) by solar axions produced via the Primakoff effect. The mass bound assumes the KSVZ axion model, $S = 0.5$, and $m_u/m_d = 0.56$. They set a limit on the product of axion couplings to photons and nucleons as $G_{A\gamma\gamma} \cdot g_{App} < 1.44\times10^{-14}$ GeV^{-1} (90 % CL).

[13] ABDELHAMEED 20 look for the resonant excitation of ^{169}Tm (8.41 keV) by solar axions produced via the axion-electron coupling. They set a limit on the product of axion couplings to electrons and nucleons as $g_{Aee} \cdot g_{App} < 2.81\times10^{-16}$ (90 % CL).

[14] APRILE 20 look for solar axions from the ABC interactions, the Primakoff conversion, and the 14.4 keV M1 transition of ^{57}Fe. An excess is observed at low energies between 2 and 3 keV. See their Fig.8 for correlation between the couplings.

[15] KLIMCHITSKAYA 20 use the measurement of the Casimir force between a Au-coated microsphere and a SiC plate to constrain the force due to two-axion exchange for 17.8 $< m_{A^0} <$ 100 eV. See their Fig. 2 for mass-dependent limits.

[16] WANG 20A is an update of LIU 17A. The limit assumes the DFSZ axion. See their Fig. 7 for the limit on product of axion couplings to electrons and nucleons.

[17] LEINSON 19 is analogous to BEZNOGOV 18, but estimating the axion luminosity based on the Tolman's analytic solution to the Einstein equations of spherical fluids in hydrostatic equilibrium. The dimensionless axion-neutron coupling is constrained as $g_{Ann} < 1.0\times10^{-10}$.

[18] LLOYD 19 is analogous to BERENJI 16. They highlight that the limit obtained with this technique strongly depends on the assumed NS core temperature.

[19] SMORRA 19 look for spin-precession effects from ultra-light axion dark matter in the $\overline{p}$ spin-flip resonance data. Assuming $\rho_A = 0.4$ GeV/cm^3, they constrain the dimensionless axion-antiproton coupling as $g_{A\overline{p}\overline{p}} < 2$–9 at 95% CL for $m_{A^0} = 2\times10^{-23}$–$4\times10^{-17}$ eV. See the right panel of their Fig. 3.

[20] WU 19 look for axion-induced time-oscillating features of the NMR spectrum of acetonitrile-2-^{13}C. Assuming $C_p = C_n$ and $\rho_A = 0.4$ GeV/cm^3, they constrain the dimensionless axion-nucleon coupling as $g_{ANN} < 6\times10^{-5}$ for $m_{A^0} = 10^{-21}$–1.3×10^{-17} eV. Note that the limits for $m_{A^0} < 10^{-21}$ eV in their Fig. 3(a) should be weaker than those for heavier masses. See ADELBERGER 19 and WU 19C on this issue.

[21] AKHMATOV 18 is an update of GAVRILYUK 15.

[22] ARMENGAUD 18 is analogous to ALESSANDRIA 13. The quoted limit assumes the DFSZ axion model. See their Fig. 4 for the limit on product of axion couplings to electrons and nucleons.

[23] BEZNOGOV 18 constrain the axion–neutron coupling by assuming that thermal evolution of the hot neutron star HESS J1731-347 is dominated by the lowest possible neutrino emission. The quoted limit assumes the KSVZ axion with the effective Peccei-Quinn charge of the neutron $C_n = -0.02$. The dimensionless axion–neutron couling is constrained as $g_{Ann} < 2.8\times10^{-10}$.

[24] GAVRILYUK 18 look for the resonant excitation of ^{83}Kr (9.4 keV) by solar axions produced via the Primakoff effect. The mass bound assumes $m_u/m_d = 0.56$ and $S = 0.5$.

[25] HAMAGUCHI 18 studied the axion emission from the neutron star in Cassiopeia A based on the minimal cooling scenario which explains the observed rapid cooling rate. The quoted limit corresponds to $f_A > 5\times10^8$ GeV obtained for the KSVZ axion with $C_p = -0.47$ and $C_n = -0.02$.

[26] ABEL 17 look for a time-oscillating neutron EDM and an axion-wind spin-precession effect respectively induced by axion dark matter couplings to gluons and nucleons. See their Fig. 4 for limits in the range of $m_{A^0} = 10^{-24}$–10^{-17} eV.

[27] ABGRALL 17 limit assumes the hadronic axion model used in ALESSANDRIA 13. See their Fig. 4 for the limit on product of axion couplings to electrons and nucleons.

[28] FU 17A look for the 14.4 keV ^{57}Fe solar axions. The limit assumes the DFSZ axion model. See their Fig. 3 for mass-dependent limits on the axion-electron coupling. Notice that in this figure the DFSZ and KSVZ lines should be interchanged.

[29] KLIMCHITSKAYA 17A use the differential measurement of the Casimir force between a Ni-coated sphere and Au and Ni sectors of the structured disc to constrain the axion coupling to nucleons for 2.61 meV $< m_{A^0} <$ 0.9 eV. See their Figs. 1 and 2 for mass dependent limits.

[30] LIU 17 is analogous to ALESSANDRIA 13. The limit assumes the hadronic axion model. See their Fig. 6(b) for the limit on product of axion couplings to electrons and nucleons.

[31] BERENJI 16 used the Fermi LAT observations of neutron stars to look for photons from axion decay. They assume the effective Peccei-Quinn charge of the neutron $C_n = 0.1$ and a neutron-star core temperature of 20 MeV.

[32] GAVRILYUK 15 look for solar axions emitted by the M1 transition of ^{83}Kr (9.4 keV). The mass bound assumes $m_u/m_d = 0.56$ and $S = 0.5$.

[33] KLIMCHITSKAYA 15 use the measurement of differential forces between a test mass and rotating source masses of Au and Si to constrain the force due to two-axion exchange for $1.7\times10^{-3} < m_{A^0} <$ 0.9 eV. See their Figs. 1 and 2 for mass dependent limits.

[34] BEZERRA 14 use the measurement of the thermal Casimir–Polder force between a Bose-Einstein condensate of ^{87}Rb atoms and a SiO_2 plate to constrain the force mediated by exchange of two pseudoscalars for 0.1 meV $< m_{A^0} <$ 0.3 eV. See their Fig. 2 for the mass-dependent limit on pseudoscalar coupling to nucleons.

[35] BEZERRA 14A is analogous to BEZERRA 14. They use the measurement of the Casimir pressure between two Au-coated plates to constrain pseudoscalar coupling to nucleons for 1×10^{-3} eV $< m_{A^0} <$ 15 eV. See their Figs. 1 and 2 for the mass-dependent limit.

[36] BEZERRA 14B is analogous to BEZERRA 14. BEZERRA 14B use the measurement of the normal and lateral Casimir forces between sinusoidally corrugated surfaces of a sphere and a plate to constrain pseudoscalar coupling to nucleons for 1 eV $< m_{A^0} <$ 20 eV. See their Figs. 1–3 for mass-dependent limits.

[37] BEZERRA 14C is analogous to BEZERRA 14. They use the measurement of the gradient of the Casimir force between Au- and Ni-coated surfaces of a sphere and a plate to constrain pseudoscalar coupling to nucleons for 3×10^{-5} eV $< m_{A_0} <$ 1 eV. See their Figs. 1, 3, and 4 for the mass-dependent limits.

[38] BLUM 14 studied effects of an oscillating strong CP phase induced by axion dark matter on the primordial ^{4}He abundance. See their Fig. 1 for mass-dependent limits.

[39] LEINSON 14 attributes the excessive cooling rate of the neutron star in Cassiopeia A to axion emission from the superfluid core, and found $C_n^2\, m_{A^0}^2 \simeq 5.7\times10^{-6}$ eV^2, where C_n is the effective Peccei-Quinn charge of the neutron.

[40] ALESSANDRIA 13 used the CUORE experiment to look for 14.4 keV solar axions produced from the M1 transition of thermally excited ^{57}Fe nuclei in the solar core, using the axio-electric effect. The limit assumes the hadronic axion model. See their Fig. 4 for the limit on product of axion couplings to electrons and nucleons.

[41] ARMENGAUD 13 is analogous to ALESSANDRIA 13. The limit assumes the hadronic axion model. See their Fig. 8 for the limit on product of axion couplings to electrons and nucleons.

[42] BELLI 12 looked for solar axions emitted by the M1 transition of ^{7}Li* (478 keV) after the electron capture of ^{7}Be, using the resonant excitation ^{7}Li in the LiF crystal. The mass bound assumes $m_u/m_d = 0.55$, $m_u/m_s = 0.029$, and the flavor-singlet axial vector matrix element $S = 0.4$.

[43] BELLINI 12B looked for 5.5 MeV solar axions produced in the $pd \to {}^3$He A^0.The limit assumes the hadronic axion model. See their Figs. 6 and 7 for mass-dependent limits on productsof axion couplings to photons, electrons, and nucleons.

[44] DERBIN 11 looked for solar axions emitted by the M1 transition of thermally excited ^{57}Fe nuclei in the Sun, using their possible resonant capture on ^{57}Fe in the laboratory. The mass bound assumes $m_u/m_d = 0.56$ and the flavor-singlet axial vector matrix element $S = 3F - D \simeq 0.5$.

[45] BELLINI 08 consider solar axions emitted in the M1 transition of ^{7}Li* (478 keV) and look for a peak at 478 keV in the energy spectra of the Counting Test Facility (CTF), a Borexino prototype. For $m_{A^0} <$ 450 keV they find mass-dependent limits on products of axion couplings to photons, electrons, and nucleons.

[46] ADELBERGER 07 use precision tests of Newton's law to constrain a force contribution from the exchange of two pseudoscalars. See their Fig. 5 for limits on the pseudoscalar coupling to nucleons, relevant for m_{A^0} below about 1 meV.

Axion Limits from T-violating Medium-Range Forces

The limit is for the coupling $g = g_p\, g_s$ in a T-violating potential between nucleons, nucleon and electron, or electrons of the form $V = \frac{g\hbar^2}{8\pi m_p}(\boldsymbol{\sigma}\cdot\hat{\boldsymbol{r}})\,(\frac{1}{r^2} + \frac{1}{\lambda r})\, e^{-r/\lambda}$, where g_s and g_p are dimensionless scalar and pseudoscalar coupling constants, m_p is the fermion mass with the pseudoscalar coupling (whereas the mass m_s of the fermion with the scalar coupling does not explicitly appear), and $\lambda = \hbar/(m_A c)$ is the range of the force.

[1] AYRES 23 at PSI use their neutron EDM setup to look for a mm to micron-range spin-dependent force between ultracold spin-polarized neutrons stored in vacuum and the unpolarised nucleons in the surrounding apparatus. They constrain a nucleon-neutron monopole-dipole interaction parameterised by the coupling $g_s^N g_p^n$. They set a limit of $g_s^N g_p^n < 10^{-20}$ (95% CL) for a 1 meV mass axion, see Fig. 6.

[2] PODDAR 23 search for long-range monopole-dipole forces between the polarized population of electrons inside the Earth and the unpolarised nucleons in the Sun, which would affect the precession of orbital perihelion. However, the most competitive limit is obtained by combining the monopole-monopole force constraints on g_s^N from planetary precession with the strongest stellar bound on the pseudoscalar electron coupling (g_p^e), shown in Fig. 5.

[3] ZHANG 23 look for changes of the ratio of precession frequencies between ^{129}Xe and ^{131}Xe as the bias field is flipped in Earth's gravitational field after Earth roation effect is subtracted. They find $g_p^n g_s^N < 1\times10^{-26}$–$3.7\times10^{-36}$ for $\lambda = 0.3$–1×10^{10} m. See their Fig. 4 for limits as a function of λ.

[4] CRESCINI 22 is an update of CRESCINI 17, and find $g_p^e g_s^N \leq 5.7 \times 10^{-32}$ and $g_p^e g_s^e \leq 1.6 \times 10^{-31}$ for $\lambda \gtrsim 10$ cm at 95% CL. See their Fig. 4 for limits as a function of λ.

[5] FENG 22 look for changes of the ratio of precession frequencies between ^{129}Xe and ^{131}Xe when a BGO crystal is positioned near the atomic cell. They find $g_p^n g_s^N < 2\times10^{-20}$–$3\times10^{-24}$ for $\lambda = 0.11$–0.55 mm. See their Fig. 4 for limits as a function of λ.

[6] AFACH 21 look for axion domain walls coupled to atomic spins by using the global network of optical magnetometers. Assuming that the axion domain walls make up all dark matter, they exclude the effective decay constant below 4×10^5 GeV for m_{A^0} in the range of 10^{-15}–10^{-11} eV. See their Fig. 4 for the mass-dependent limits.

[7] DZUBA 18 used atomic EDM measurements to derive limits on the product of the pseudoscalar coupling to nucleon and the scalar coupling to electron, which improved on the laboratory bounds for $m_{A^0} > 0.01$ eV. See their Fig. 1 for mass-dependent limits.

[8] STADNIK 18 used atomic and molecular EDM experiments to derive limits on the product of the pseudoscalar couplings to electron and the scalar coupling to nucleon and electron. See their Fig. 2 for mass-dependent limits, which improved on the laboratory bounds for $m_{A^0} > 0.01$ eV.

[9] CRESCINI 17 use the QUAX-$g_p g_s$ experiment to look for variation of a paramagnetic GSO crystal magnetization when rotating lead disks are positioned near the crystal, and find $g = g_p^e g_s^N < 4.3\times10^{-30}$ for $\lambda = 0.1$–0.2 m at 95% CL. See their Fig. 6 for limits as a function of λ.

[10] AFACH 15 look for a change of spin precession frequency of ultracold neutrons when a magnetic field with opposite directions is applied, and find $g < 2.2\times10^{-27}$ $(\mathrm{m}/\lambda)^2$ at 95% CL for $1\ \mu\mathrm{m} < \lambda < 5$ mm. See their Fig. 3 for their limits.

[11] STADNIK 15 studied proton and neutron spin contributions for nuclei and derive the limits $g < 10^{-28}$–10^{-23} for $\lambda > 3\times10^{-4}$ m using the data of TULLNEY 13. See their Figs. 1 and 2 for λ-dependent limits.

[12] TERRANO 15 used a torsion pendulum and rotating attractor, and derived a restrictive limit on the product of the pseudoscalar coupling to electron and the scalar coupling to nucleons, $g < 9\times10^{-29}$–5×10^{-26} for $m_{A^0} < 1.5$–400 μeV. See their Fig. 5 for mass-dependent limits.

[13] BULATOWICZ 13 looked for NMR frequency shifts in polarized ^{129}Xe and ^{131}Xe when a zirconia rod is positioned near the NMR cell, and find $g < 1\times10^{-19}$–1×10^{-24} for $\lambda = 0.01$–1 cm. See their Fig. 4 for their limits.

[14] CHU 13 look for a shift of the spin precession frequency of polarized ^{3}He in the presence of an unpolarized mass, in analogy to YOUDIN 96. See Fig. 3 for limits on g in the approximate m_{A^0} range 0.02–2 meV.

[15] TULLNEY 13 look for a shift of the precession frequency difference between the colocated ^{3}He and ^{129}Xe in the presence an unpolarized mass, and derive limits $g < 3\times10^{-29}$–2×10^{-22} for $\lambda > 3\times10^{-4}$ m. See their Fig. 3 for λ-dependent limits.

[16] RAFFELT 12 show that the pseudoscalar couplings to electron and nucleon and the scalar coupling to nucleon are individually constrained by stellar energy-loss arguments and searches for anomalous monopole-monopole forces, together providing restrictive constraints on g. See their Figs. 2 and 3 for results.

[17] HOEDL 11 use a novel torsion pendulum to study the force by the polarized electrons of an external magnet. In their Fig. 3 they show restrictive limits on g in the approximate m_{A^0} range 0.03–10 meV.

[18] PETUKHOV 10 use spin relaxation of polarized ^{3}He and find $g < 3\times10^{-23}$ $(\mathrm{cm}/\lambda)^2$ at 95% CL for the force range $\lambda = 10^{-4}$–1 cm.

[19] SEREBROV 10 use spin precession of ultracold neutrons close to bulk matter and find $g < 2\times10^{-21}$ $(\mathrm{cm}/\lambda)^2$ at 95% CL for the force range $\lambda = 10^{-4}$–1 cm.

[20] IGNATOVICH 09 use data on depolarization of ultracold neutrons in material traps. They show λ-dependent limits in their Fig. 1.

[21] SEREBROV 09 uses data on depolarization of ultracold neutrons stored in material traps and finds $g < 2.96\times10^{-21}$ $(\mathrm{cm}/\lambda)^2$ for the force range $\lambda = 10^{-3}$–1 cm and $g < 3.9\times10^{-22}$ $(\mathrm{cm}/\lambda)^2$ for $\lambda = 10^{-4}$–10^{-3} cm, each time at 95% CL, significantly improving on BAESSLER 07.

[22] BAESSLER 07 use the observation of quantum states of ultracold neutrons in the Earth's gravitational field to constrain g for an interaction range 1 μm–a few mm. See their Fig. 3 for results.

[23] HECKEL 06 studied the influence of unpolarized bulk matter, including the laboratory's surroundings or the Sun, on a torsion pendulum containing about 9×10^{22} polarized electrons. See their Fig. 4 for limits on g as a function of interaction range.

[24] NI 99 searched for a T-violating medium-range force acting on paramagnetic Tb F_3 salt. See their Fig. 1 for the result.

[25] POSPELOV 98 studied the possible contribution of T-violating Medium-Range Force to the neutron electric dipole moment, which is possible when axion interactions violate CP. The size of the force among nucleons must be smaller than gravity by a factor of 2×10^{-10} $(1\ \mathrm{cm}/\lambda_A)$, where $\lambda_A = \hbar/m_A c$.

[26] YOUDIN 96 compared the precession frequencies of atomic ^{199}Hg and Cs when a large mass is positioned near the cells, relative to an applied magnetic field. See Fig. 3 for their limits.

[27] RITTER 93 studied the influence of bulk mass with polarized electrons on an unpolarized torsion pendulum, providing limits in the interaction range from 1 to 100 cm.

[28] VENEMA 92 looked for an effect of Earth's gravity on nuclear spin-precession frequencies of ^{199}Hg and ^{201}Hg atoms.

[29] WINELAND 91 looked for an effect of bulk matter with aligned electron spins on atomic hyperfine resonances in stored ^{9}Be$^+$ ions using nuclear magnetic resonance.

Hidden Photons: Kinetic Mixing Parameter Limits

Limits are on the kinetic mixing parameter χ which is defined by the Lagrangian

$$L = -\tfrac{1}{4} F_{\mu\nu}F^{\mu\nu} - \tfrac{1}{4} F'_{\mu\nu}F'^{\mu\nu} - \tfrac{\chi}{2} F_{\mu\nu}F'^{\mu\nu} + \frac{m_{\gamma'}^2}{2} A'_\mu A'^\mu,$$

where A_μ and A'_μ are the photon and hidden-photon fields with field strengths $F_{\mu\nu}$ and $F'_{\mu\nu}$, respectively, and $m_{\gamma'}$ is the hidden-photon mass.

[1] ABREU 24 look for hidden photons produced from the pp collision in the decay channel $\gamma' \to e^+e^-$, and exclude at 90% CL the region of $\chi = 4\times10^{-6}$–2×10^{-4} and $m_{\gamma'}$ = 10–80 MeV, with the newly excluded region near the higher values of χ. See their Fig. 7 for mass-dependent limits.

[2] AAD 23BO look for rare decays of the Z boson, $Z \to \gamma' + H'$, with dark Higgs decaying into a pair of hidden photons, assuming that at least two of the hidden photons decay into e^+e^- or $\mu^+\mu^-$. The quoted limit assumes the hidden fine structure constant $\alpha_D = 0.1$ and the dark Higgs mass ranging 20 to 70 GeV. See their Fig.5 for the mass-dependent limits.

[3] AAD 23I look for exotic decays of the SM-like Higgs boson, $H \to \gamma'\gamma'$ with hidden photons decaying into displaced lepton or light quark pairs, and set limits on the kinetic mixing within 1×10^{-4}–1×10^{-8} for the given mass range. The quoted limit is for $m_{A^0} \simeq$ 13 GeV with a branching fraction of 0.1 for the Higgs decaying into hidden photon pairs. See their Fig. 13 for the mass-dependent limits.

[4] AAD 23T is analogous to AAD 22S, but using the ZH production mode, and set the upper limit on the branching ratio B($H \to \gamma\gamma'$) within 0.0219–0.0252 (95% CL).

[5] AALBERS 23A look for an absorption of hidden photon dark matter. The quoted limit is for $m_{\gamma'}$ = 1.4 keV. The local density $\rho_{\gamma'}$ = 0.3 GeV/cm^3 is assumed. See their Fig. 7 for mass-dependent limits.

[6] ABLIKIM 23AF look for invisible decays of hidden photons produced in the reaction $e^+e^- \to \gamma\gamma'$. They set limits within the 1.6×10^{-3}–5.7×10^{-3}. See their Fig. 3 for mass-dependent limits.

[7] ABUDINEN 23B look for hidden photons in the dark Higgsstrahlung process, $e^+e^- \to \gamma' H'$ ($\gamma' \to \mu^+\mu^-$) with H' being invisible. They set upper limits on the product of the kinetic mixing and the hidden gauge coupling, $\chi^2\cdot\alpha_D$, in the range of 1.7×10^{-8}–2×10^{-6} at 90% CL for a 1 GeV dark Higgs mass. See their Fig. 3 for the mass-dependent limits.

[8] ADHIKARI 23 look for the annual modulation signal induced by solar flux of hidden photons. See their Fig. 10 for mass-dependent limits.

[9] ADHIKARI 23A look for absorption and Compton-like processes of hidden photon dark matter. The quoted limit is for $m_{\gamma'} \simeq$ 12 keV. Limits between 6×10^{-14}–3×10^{-11} are obtained. See their Fig. 4 for mass-dependent limits.

[10] ADRIAN 23 is an update of ADRIAN 18, and use the data from the 2016 engineering run at 2.3 GeV. The quoted limit is at $m_{\gamma'} \simeq$ 74 MeV. See their Fig. 28 for the mass-dependent limits.

[11] AGNES 23A look for an absorption of hidden photon dark matter. The quoted limit is for $m_{\gamma'}$ = 0.03 keV. The local density $\rho_{\gamma'}$ = 0.3 GeV/cm^3 is assumed. See their Fig. 2 for mass-dependent limits.

[12] AN 23A look for absorption of hidden photon dark matter at radio telescopes, setting limits based on data from the FAST telescope. The local density $\rho_{\gamma'}$ = 0.3 GeV/cm^3 is assumed. See their Fig. 1 for mass-dependent limits.

[13] ANDREEV 23 is an update of ANDREEV 21 and ANDREEV 21A. The quoted limit applies to $m_{\gamma'}$ = 1 MeV. See their Fig. 3 for mass-dependent limits.

[14] BAJJALI 23 look for hidden photon dark matter by using a 12–18 GHz dish antenna at U. Hamburg that is sensitive to vertically aligned hidden photon polarizations. They assume a local density of $\rho_{\gamma'}$ = 0.3 GeV/cm^3. See their Figure 12 for mass-dependent limits in the range of $m_{\gamma'}$ = 50–75 μeV under the assumption of randomly aligned hidden photon polarizations, defined as "1 sigma sensitivity". The run is labelled BRASS-p.

[15] CORTINA-GIL 23C NA62 beam dump experiment searches for hidden photons decaying to $\mu^+\mu^-$, extending their previous search CORTINA-GIL 19. The quoted limit applies at 300 MeV but does not extend to arbitrarily large kinetic mixing parameters. See Fig. 4 for mass-dependent limits.

[16] HAYRAPETYAN 23G search for kinetically mixed hidden photons in proton-proton collisions at the LHC that would generate a narrow peak in the mass spectrum of dimuon events. The mass window between 2.6 and 4.2 GeV is left unconstrained to avoid J/ψ and $\psi(2S)$ resonances. Mass dependent limits given in their Fig. 6.

[17] KOTAKA 23 is an update of TOMITA 20, and set limits $\chi <$ 0.3–2×10^{-10} for the quoted mass range. The local density $\rho_{\gamma'}$ = 0.39 GeV/cm^3 is assumed. See their Fig. 5 for mass-dependent limits.

[18] LI 23I set cooling bounds on the emission of hidden photons from the Sun, red giant, and horizontal branch stars, including emission of both the transverse and longitudinal modes. Cooling bounds are computed assuming a static model as opposed to considering the impact on stellar evolution. The result is comparable to earlier estimates of the same bound e.g. REDONDO 13. Limit applies at the most constraining mass around 200 eV for the solar bound.

[19] RAMANATHAN 23 look for hidden photon dark matter using a gold-plated copper dish antenna cooled to 20 mK. The local density $\rho_{\gamma'}$ = 0.45 GeV/cm^3 is assumed. Limits between 7.9×10^{-13} and 3.81×10^{-12} are obtained. See their Fig. 5 for mass-dependent limits.

[20] ROMANENKO 23 employed two superconducting radio frequency cavities with a high quality factor, optimized for detecting the longitudinal polarization of the hidden photon. The quoted limit is set at $m_{\gamma'} \simeq 5\mu$eV. See their Fig. 4 for the mass-dependent limits.

[21] XIA 23 is analogous to WU 22A and use the Fermi-LAT pulsar timing array. They set a bound on the local density as $\rho_{\gamma'} \lesssim$ 7 GeV/cm^3 for $m_{\gamma'} \lesssim 10^{-23}$ eV at 95% CL, with weaker constraints up to 10^{-22} eV. See their Fig. 1 for the mass-dependent limits.

[22] AAD 22J look for exotic decays of the SM-like Higgs boson, $H \to \gamma'\gamma' \to 4\ell$ and $H \to Z\gamma' \to 4\ell$, and set limits on the kinetic mixing and the Higgs portal coupling. See their Figs. 19 and 20 for the mass-dependent limits.

[23] AAD 22S look for decays of a Higgs boson into γ and γ' using the VBF production mode, and set the upper limit on the branching ratio at 0.018 (95% CL) for the 125 GeV Higgs boson. For the quoted mass range, the signal acceptance changes by less than 1%.

[24] APRILE 22 is analogous to AN 20, and set limits $\chi < 3\times10^{-13}$ (eV/$m_{\gamma'}$) for $m_{\gamma'} <$ 3 eV (90% C.L.). For $m_{\gamma'} > 3$ eV, see their Fig. 16 for mass-dependent limits.

[25] APRILE 22 extend APRILE 19 to lower masses by removing the background of ionization signals correlated with high-energy events. The quoted limit applies to $m_{\gamma'} = 0.09$ keV. See their Fig. 15 for mass-dependent limits.

[26] APRILE 22B is an update of APRILE 20, and set limits $\chi \lesssim 5\times10^{-17}$–$2\times10^{-13}$. The quoted limit applies to $m_{\gamma'} = 1$ keV. They exclude the XENON1T excess found in APRILE 20. See their Fig. 6 for mass-dependent limits.

[27] BATTAGLIERI 22 is analogous to BATELL 14, and derived limits from the electron beam dump experiment at Jefferson Lab (BDX-MINI). Limits at the level of 7×10^{-5}–1×10^{-2} are obtained for the dark matter mass $m_{\gamma'}/3$ and the hidden gauge coupling $\alpha_D = 0.1$. See their Fig. 11.

[28] BOLTON 22 use the Ly-α forest at $z \simeq 0.1$ as a calorimeter for heating in the intergalactic medium by the resonant conversion of hidden photon dark matter to photons, which is assumed to be responsible for the tension between the predicted and observed Ly-α absorption linewidths.

[29] CERVANTES 22 use a dielectrically loaded Fabry-Perot open cavity to look for hidden photon dark matter. The local density $\rho_{\gamma'} = 0.45$ GeV/cm^3 is assumed. See their Fig. 5 for mass-dependent limits.

[30] CHILES 22 look for hidden photon dark matter by using a layered dielectric target and a superconducting nanowire single-photon detector. The local density $\rho_{\gamma'} = 0.4$ GeV/cm^3 is assumed. See their Fig. 4 for mass-dependent limits.

[31] HOCHBERG 22 update HOCHBERG 19. The quoted limit applies to $m_{A^0} \simeq 11$ eV. See their Fig. 5 for mass-dependent limits.

[32] LEES 22 look for a hidden fermion-fermion bound state decaying into three hidden photons, which subsequently decay into e^+e^-, $\mu^+\mu^-$, or $\pi^+\pi^-$. For the bound-state mass in the range of 0.05–9.5 GeV, limits at the level of 5×10^{-5}–1×10^{-3} are obtained. See their Fig. 6 for mass-dependent limits.

[33] LU 22 derive the limit by studying the effect of photons oscillating into hidden photons on the surface luminosity of the neutron star RX J1856.6-3754.

[34] MANENTI 22 look for hidden photon dark matter by using a multilayer dielectric haloscope. Limits between 6.86×10^{-11} and 5×10^{-8} are obtained for $m_{\gamma'} \simeq$ 1.1–3.1 eV. See their Fig. 11 for mass-dependent limits.

[35] THOMAS 22 improved KRIBS 21 by taking account of the changes in the parton distribution functions due to the inclusion of hidden photons. The quoted limit is at $m_{\gamma'} \simeq$ 4 GeV. Limits in the range of 3×10^{-2}–9×10^{-2} are obtained for $m_{\gamma'} =$ 1–80 GeV. See their Fig. 1 for the limits.

[36] TUMASYAN 22AH look for exotic decays of the SM-like Higgs boson, $H \to Z\gamma' \to 4\ell$, and set limits on the Higgs portal coupling. See their Fig. 6 for the limits.

[37] TUMASYAN 22N look for exotic decays of the SM-like Higgs boson, $H \to \gamma'\gamma'$ ($\gamma' \to \mu^+\mu^-$), and set limits on the branching fraction product. See their Fig. 7 for mass- and lifetime-dependent limits.

[38] WU 22A look for direction-dependent oscillations in the gravitational potential generated by ultralight hidden photon dark matter, and set a bound on its local density as $\rho_{\gamma'} \lesssim$ 5 GeV/cm^3 for $m_{\gamma'} \lesssim 10^{-23}$ eV at 95% CL.

[39] ANDREEV 21 is analogous to BANERJEE 18A. The quoted limit applies to $m_{\gamma'} = 1$ MeV. See their Fig. 3 for mass-dependent limits.

[40] ANDREEV 21A extends the limits of BANERJEE 19 by taking account of production through the resonant annihilation of secondary positrons with atomic electrons. The quoted limit is at $m_{\gamma'} = 0.23$ GeV, assuming the fermion dark matter of mass $m_{\gamma'}/3$ and the hidden gauge coupling $\alpha_D = 0.1$. See their Fig.3 for mass-dependent limits.

[41] BI 21 look for the gamma-ray spectral attenuation due to scattering with hidden photons constituting all dark matter, using the measurements of sub-PeV gamma-rays from the Crab Nebula by the Tibet ASγ and HAWC experiments, together with MAGIC and HEGRA gamma-ray data. See their Fig. 4 for mass-dependent limits.

[42] CAZZANIGA 21 look for semi-visible decays of hidden photons, $\gamma' \to \chi_1\chi_2$ ($\chi_2 \to \chi_1 e^+e^-$), where χ_1 and χ_2 are hidden fermions. They exclude $3\times10^{-5} \lesssim \chi \lesssim 2\times10^{-2}$ assuming the hidden gauge coupling $\alpha_D = 0.1$, and the fermion masses $m_{\chi_1} = m_{\gamma'}/3$, $(m_{\chi_2} - m_{\chi_1})/m_{\chi_1} = 0.4$. See their Fig. 4 for mass-dependent limits.

[43] DIXIT 21 look for hidden photon dark matter by using a superconducting transmon qubit dispersively coupled to a high Q storage cavity. The local density $\rho_{\gamma'} = 0.4$ GeV/cm^3 is assumed. See their Fig.4 for mass-dependent limits.

[44] GHOSH 21 use existing haloscope axion search limits to set limits on hidden photon dark matter, considering the polarization of hidden photons. The quoted limit is at $m_{\gamma'} \simeq 3$ μeV. See their Fig. 1 for mass-dependent limits.

[45] GODFREY 21 look for hidden photon dark matter by using a wideband antenna, and set 5σ limits on χ. The local density $\rho_{\gamma'} = 0.38$ GeV/cm^3 is assumed. See their updated Fig. 12 in arXiv:2101.02805v4 for mass-dependent limits in the range of $m_{\gamma'} = 0.207$–1.24 μeV.

[46] KOPYLOV 21A is an update of KOPYLOV 19, but use Ne gas instead of Ar. The quoted limit applies to $m_{\gamma'} = 12$ eV. See their Fig. 4 for mass-dependent limits.

[47] KRIBS 21 used the HERA data on neutral current deep inelastic ep scattering to derive the limits, which become weaker for heavier masses. See their Fig. 3 for mass-dependent limits.

[48] SCHMIDT 21 use the microscopic Parton-Hadron-String Dynamics approach to extract limits by comparing the theoretically calculated dilepton spectra with the HADES data on the search for $\gamma' \to e^+e^-$. See their Fig. 5 for the mass-dependent limits for various allowed surplus of the hidden photon contribution over the standard model yield.

[49] TSAI 21 update the limits from the CHARM and NuCal experiments, taking account of additional production channels from proton bremsstrahlung and η meson decays, respectively. Limits between 3×10^{-8} and 1×10^{-4} are obtained for $0.01 < m_{\gamma'} < 0.8$ GeV (see their Fig. 1).

[50] AAIJ 20C look for hidden photons produced from the pp collision in the decay channel $\gamma' \to \mu^+\mu^-$. For prompt decaying hidden photons, limits at the level of 10^{-4}–10^{-3} are obtained for $m_{\gamma'} = 0.214$–30 GeV. See their Fig. 2 for mass-dependent limits.

[51] AAIJ 20C look for hidden photons produced from the pp collision in the decay channel $\gamma' \to \mu^+\mu^-$. For hidden photons with lifetimes of order ps, limits at the level of 10^{-5} are obtained for $m_{\gamma'} = 218$–315 MeV. See their Fig. 4 for mass-dependent limits.

[52] ABLIKIM 20AB search for $J/\psi \to \eta'\gamma'$ ($\gamma' \to \gamma\pi^0$), and set the upper limit on the product branching fraction of order 10^{-7}. See their Fig. 7 for mass-dependent limits.

[53] AGOSTINI 20 is analogous to ABE 14F. The quoted limit applies to $m_{\gamma'} = 150$ keV. The local density $\rho_{\gamma'} = 0.3$ GeV/cm^3 is assumed. Their limits in their Fig. 3 were later found to be incorrect due to an error of their Eqs. (1) and (2). See Fig. 3 in AGOSTINI 22A for the corrected limits.

[54] AMARAL 20 use a second-generation SuperCDMS high-voltage eV-resolution detector to set limits on dark-matter hidden photon absorption. The quoted limit is for $m_{\gamma'} \simeq$ 17 eV. The local density $\rho_{\gamma'} = 0.3$ GeV/cm^3 is assumed. See their Fig. 3 for mass-dependent limits.

[55] AN 20 updates the direct detection limit of AN 13C on solar flux of hidden photons; $\chi < 1.6\times10^{-12}$ (eV/$m_{\gamma'}$) for $m_{\gamma'} < 6$ eV (90% C.L.). For $m_{\gamma'} > 6$ eV, see their Fig. 1 for mass-dependent limits.

[56] ANDRIANAVALOMAHEFA 20 is analogous to SUZUKI 15, but uses a mirror that is about one order of magnitude larger than in similar studies in the past. Limits at the level of 10^{-12} are obtained for $m_{\gamma'} =$ 2.5–7 eV. See their Fig.23 and Table III for mass-dependent limits.

[57] APRILE 20 is analogous to ABE 14F, and set limits $\chi \lesssim 10^{-16}$–10^{-12}. The quoted limit applies to $m_{\gamma'} = 1$ keV. They also found an excess over known backgrounds, which favors the mass $m_{\gamma'} = 2.3 \pm 0.2$ keV with a 3 σ significance. See their Fig. 10 for mass-dependent limits.

[58] ARALIS 20 is analogous to ABE 14F. The quoted limit applies to $m_{\gamma'} = 0.1$ keV. The local density $\rho_{\gamma'} = 0.3$ GeV/cm^3 is assumed. The limits at masses above 3 keV in their Fig. 10 was later found to be incorrect due to an error in their analysis. See Fig. 3 in ARALIS 21 for the corrected limits.

[59] ARGUELLES 20 examine hidden-photon production in atmospheric cosmic-ray showers and its decay in IceCube and Super-Kamiokande. The quoted limit assumes a lifetime of $c\tau = 0.1$ km. See their Fig. 16 for mass- and lifetime-dependent limits.

[60] ARNAUD 20 look for the absorption signal of hidden photon dark matter in a Ge detector. The quoted limit applies to $m_{\gamma'} \simeq 9$ eV. The local density $\rho_{\gamma'} = 0.3$ GeV/cm^3 is assumed. See their Fig. 3 for mass-dependent limits.

[61] BANERJEE 20 is an update of BANERJEE 18. They exclude $8.2\times10^{-5} \lesssim \chi \lesssim 1\times10^{-2}$ for $m_{\gamma'} =$ 1.5–24 MeV. In particular, they exclude $\chi = 1.2\times10^{-4}$–6.8×10^{-4} for the 16.7 MeV gauge boson. See their Fig. 5 for mass-dependent limits.

[62] BARAK 20 is analogous to AGUILAR-AREVALO 19A, and look for hidden photon dark matter by using the Skipper CCD. The quoted limit applies to $m_{\gamma'} = 12.8$ eV. See their Fig. 4 for mass-dependent limits.

[63] KRASNIKOV 20 showed that the limit of BANERJEE 20 combined with the measured anomalous magnetic moment of the electron exclude the 16.7 MeV gauge boson suggested by the ATOMKI (KRASZNAHORKAY 16) experiment if it has pure vector or axial-vector interactions.

[64] SHE 20 look for solar hidden photons. The quoted limit applies to $m_{\gamma'} = 180$ eV. See their Fig. 4 for mass-dependent limits.

[65] SHE 20 look for hidden photon dark matter and set limits $\chi < 1.3\times10^{-15}$–2.8×10^{-14} for the quoted mass range. The local density $\rho_{\gamma'} = 0.3$ GeV/cm^3 is assumed. See their Fig. 6 for mass-dependent limits.

[66] SIRUNYAN 20AQ look for a narrow resonance decaying into a pair of muons. For $m_{\gamma'} <$ 45 GeV, they use dedicated high-rate dimuon triggers to reduce the muon transverse momentum thresholds. The quoted limit applies to $m_{\gamma'} = 50$ GeV, and limits of order 10^{-3} are obtained for the quoted mass range. See their Fig. 3 for mass-dependent limits.

[67] TOMITA 20 look for hidden photon dark matter using a planar metal plate and cryogenic receiver and set limits $\chi < 1.8$–4.3×10^{-10} for the quoted mass range. The local density $\rho_{\gamma'} = 0.39$ GeV/cm^3 is assumed. See their Fig. 7 for mass-dependent limits.

[68] WANG 20A is analogous to ABE 14F. The quoted limit applies to $m_{\gamma'} = 185$ eV. The local density $\rho_{\gamma'} = 0.3$ GeV/cm^3 is assumed. See their Fig. 11 for mass-dependent limits.

[69] AABOUD 19G look for $h \to \gamma'\gamma'$ ($\gamma' \to \mu^+\mu^-$) and exclude a kinetic mixing around 10^{-9}–10^{-8} for B($h \to \gamma'\gamma'$) = 0.01 and 0.1. See their Fig. 9 for mass-dependent limits.

[70] ABLIKIM 19A look for $J/\psi \to \gamma'\eta$ ($\gamma' \to e^+e^-$). Limits between 6×10^{-3} and 5×10^{-2} are obtained (see their Fig. 8).

[71] ABLIKIM 19H look for $J/\psi \to \gamma'\eta'$ ($\gamma' \to e^+e^-$). Limits between 3.4×10^{-3} and 2.6×10^{-2} are obtained. See their Fig. 5 for mass-dependent limits.

[72] AGUILAR-AREVALO 19A look for the absorption signal of hidden photon dark matter by using a CCD. The quoted limit applies to $m_{\gamma'} = 17$ eV. The local density $\rho_{\gamma'} = 0.3$ GeV/cm^3 is assumed. See their Fig. 4 for mass-dependent limits.

[73] APRILE 19D is analogous to ABE 14F. The quoted limit applies to $m_{\gamma'} = 0.7$ keV. See their Fig. 5(f) for mass-dependent limits.

[74] BANERJEE 19 is an update of BANERJEE 18A. The quoted limit is at $m_{\gamma'} = 1$ MeV. See their Fig. 3 for mass-dependent limits.

Gauge & Higgs Boson Particle Listings

Axions (A^0) and Other Very Light Bosons

[75] BHOONAH 19 examine heating of Galactic Center gas clouds by hidden photon dark matter. The quoted limit applies to $m_{\gamma'} \simeq 10^{-12}$ eV. See their Fig. 2 for mass-dependent limits.

[76] BRUN 19 is analogous to SUZUKI 15. The limit is derived under an assumption that hidden photons constitute the local dark matter density $\rho_{\gamma'} = 0.3$ GeV/cm^3.

[77] CORTINA-GIL 19 look for an invisible hidden photon in the reaction $K^+ \to \pi^+\pi^0$ ($\pi^0 \to \gamma\gamma'$). The quoted limit applies to $m_{\gamma'} = 62.5$–65 MeV. See their Figs. 6 and 7 for mass-dependent limits.

[78] DANILOV 19 examined the hidden photon production in nuclear reactors, correctly taking account of the effective photon mass in the reactor and detector. The limit gets weaker for $m_{\gamma'}$ less than the effective photon mass in proportion to $1/m^2_{\gamma'}$. See their Fig. 1 for mass-dependent limits.

[79] HOCHBERG 19 look for the absorption signal of hidden photon dark matter by using superconducting-nanowire single-photon detectors. The quoted limit applies to $m_{\gamma'} \simeq$ 1 eV. The local density $\rho_{\gamma'} = 0.3$ GeV/cm^3 is assumed. See their Fig. 4 for mass-dependent limits.

[80] KOPYLOV 19 look for hidden-photon dark matter using a counter with an aluminum cathode and derive limits assuming it constitute all the local dark matter. The quoted limit applies to $m_{\gamma'} = 12$ eV. See their Fig. 7 for mass-dependent limits.

[81] KOVETZ 19 examine heating of the early Universe plasma by hidden photon dark matter, and derive the limits by requiring that the cosmic mean 21 cm brightness temperature relative to the CMB temperature satisfy $T_{21} > -100$ mK. The quoted limit applies to $m_{\gamma'} \simeq 2\times10^{-14}$ eV. See their Fig. 3 for mass-dependent limits.

[82] NGUYEN 19 look for hidden photon dark matter with a resonant cavity, and set limits $\sim 10^{-12}$ for $m_{\gamma'} = 0.2$–2.07μeV. The quoted limit applies to $m_{\gamma'} = 1.3$ μeV. The local density $\rho_{\gamma'} = 0.3$ GeV/cm^3 is assumed. See their Fig. 19 for mass-dependent limits.

[83] ABE 18F is an update of ABE 14F. The quoted limit applies to $m_{\gamma'} \simeq 40$ keV. See their Fig. 5 for mass-dependent limits.

[84] ADRIAN 18 look for a hidden photon resonance in the reaction $e^- Z \to e^- Z\gamma'$ ($\gamma' \to e^+e^-$). The quoted limit applies to $m_{\gamma'} = 40$ MeV. See their Fig. 4 for mass-dependent limits.

[85] ANASTASI 18B look for a hidden photon resonance in the reaction $e^+e^- \to \gamma'\gamma$ ($\gamma' \to \mu^+\mu^-$). The quoted limit is obtained by combining the result of ANASTASI 16 and it applies to $m_{\gamma'} \simeq 519$–987 MeV. See their Fig. 9 for mass-dependent limits.

[86] ARMENGAUD 18 is analogous to ABE 14F. The quoted limits applies to $m_{\gamma'} = 1.6$ keV. See the right panel of Fig. 5 for mass-dependent limits.

[87] BANERJEE 18 look for hidden photons produced in the reaction $e^- Z \to e^- Z\gamma'$ ($\gamma' \to e^+e^-$), and exclude $9.2\times10^{-5} \lesssim \chi \lesssim 1\times10^{-2}$ for $m_{\gamma'} = 1$–23 MeV. They also set a limit on the electron coupling to a 16.7 MeV gauge boson suggested by the ATOMKI (KRASZNAHORKAY 16) experiment. See their Fig. 3 for mass-dependent limits.

[88] BANERJEE 18A look for invisible decays of hidden photons produced in the reaction $e^- Z \to e^- Z\gamma'$. The quoted limit is at $m_{\gamma'} = 1$ MeV. See their Fig. 15 for mass-dependent limits.

[89] KNIRCK 18 is analogous to SUZUKI 15. See their Fig. 5 for mass-dependent limits.

[90] ABGRALL 17 is analogous to ABE 14F using the MAJORANA DEMONSTRATOR. See their Fig. 3 for limits between 6 keV $< m_{\gamma'} <$ 97 keV.

[91] ABLIKIM 17AA look for $e^+e^- \to \gamma\gamma'$ ($\gamma' \to e^+e^-$ or $\mu^+\mu^-$). Limits between 10^{-3} and 10^{-4} are obtained (see their Fig. 3).

[92] ANGLOHER 17 is analogous to ABE 14F. The quoted limit is at $m_{\gamma'} = 0.7$ keV. See their Fig. 8 for mass-dependent limits.

[93] BANERJEE 17 look for invisible decays of hidden photons produced in the reaction $e^- Z \to e^- Z\gamma'$. The quoted limit applies to $m_{\gamma'} = 2$ MeV. See their Fig. 3 for mass-dependent limits.

[94] CHANG 17 examine the hidden photon emission from SN1987A, including the effects of finite temperature and density on χ and obtain limits $\chi\,(m_{\gamma'}/\text{MeV}) \lesssim 3\times10^{-9}$ for $m_{\gamma'} <$ 15 MeV and $\chi \lesssim 10^{-9}$ for $m_{\gamma'} = 15$–120 MeV.

[95] DUBININA 17 look for $\mu^+ \to e^+\overline{\nu}_\mu\nu_e\gamma'$ ($\gamma' \to e^+e^-$) in a nuclear photoemulsion. The quoted limit applies to $m_{\gamma'} = 1.1$ MeV. Limits between 4.5×10^{-3} and 10^{-2} are obtained (see their Fig. 3).

[96] LEES 17E look for invisible decays of hidden photons produced in the reaction $e^+e^- \to \gamma\gamma'$. See their Fig. 5 for limits in the mass range $m_{\gamma'} \leq 8$ GeV.

[97] AAD 16AG look for hidden photons promptly decaying into collimated electrons and/or muons, assuming that they are produced in the cascade decays of squarks or the Higgs boson. See their Fig. 10 and Fig.13 for their limits on the cross section times branching fractions.

[98] ANASTASI 16 look for the decay $\gamma' \to \pi^+\pi^-$ in the reaction $e^+e^- \to \gamma\gamma'$. Limits between 4.3×10^{-3} and 4.4×10^{-4} are obtained for 527 $< m_{\gamma'} <$ 987 MeV (see their Fig. 9).

[99] KHACHATRYAN 16 look for $\gamma' \to \mu^+\mu^-$ in a dark SUSY scenario where the SM-like Higgs boson decays into a pair of the visible lightest neutralinos with mass 10 GeV, both of which decay into γ' and a hidden neutralino with mass 1 GeV. See the right panel in their Fig. 2.

[100] AAD 15CD look for $H \to Z\gamma' \to 4\ell$ with the ATLAS detector at LHC and find $\chi < 4$–17×10^{-2} for $m_{\gamma'} = 15$–55 GeV. See their Fig. 6.

[101] ADARE 15 look for a hidden photon in $\pi^0, \eta^0 \to \gamma e^+e^-$ at the PHENIX experiment. See their Fig. 4 for mass-dependent limits.

[102] AN 15A derived limits from the absence of ionization signals in the XENON10 and XENON100 experiments, assuming hidden photons constitute all the local dark matter. Their best limit is $\chi < 1.3\times10^{-15}$ at $m_{\gamma'} = 18$ eV. See their Fig. 1 for mass-dependent limits.

[103] ANASTASI 15 look for a production of a hidden photon and a hidden Higgs boson with the KLOE detector at DAΦNE, where the hidden photon decays into a pair of muons and the hidden Higgs boson lighter than $m_{\gamma'}$ escape detection. See their Figs. 6 and 7 for mass-dependent limits on a product of the hidden fine structure constant and the kinetic mixing.

[104] ANASTASI 15A look for the decay $\gamma' \to e^+e^-$ in the reaction $e^+e^- \to e^+e^-\gamma$. Limits between 1.7×10^{-3} and 1×10^{-2} are obtained for $m_{\gamma'} = 5$–320 MeV (see their Fig. 7).

[105] BATLEY 15A look for $\pi^0 \to \gamma\gamma'$ ($\gamma' \to e^+e^-$) at the NA48/2 experiment. Limits between 4.2×10^{-4} and 8.8×10^{-3} are obtained for $m_{\gamma'} = 9$–120 MeV (see their Fig. 4).

[106] JAEGLE 15 look for the decay $\gamma' \to e^+e^-$, $\mu^+\mu^-$, or $\pi^+\pi^-$ in the dark Higgstrahlung channel, $e^+e^- \to \gamma' H'$ ($H' \to \gamma'\gamma'$) at the BELLE experiment. They set limits on a product of the branching fraction and the Born cross section as well as a product of the hidden fine structure constant and the kinetic mixing. See their Figs. 3 and 4.

[107] KAZANAS 15 set limits by studying the decay of hidden photons $\gamma' \to e^+e^-$ inside and near the progenitor star of SN1987A. See their Fig. 6 for mass-dependent limits.

[108] SUZUKI 15 looked for hidden-photon dark matter with a dish antenna and derived limits assuming they constitute all the local dark matter. Their limits are $\chi < 6\times10^{-12}$ for $m_{\gamma'} = 1.9$–4.3 eV. See their Fig. 7 for mass-dependent limits.

[109] VINYOLES 15 performed a global fit analysis based on helioseismology and solar neutrino observations, and set the limits $\chi m_{\gamma'} < 1.8\times10^{-12}$ eV for $m_{\gamma'} = 3\times10^{-5}$–8 eV. See their Fig. 11.

[110] ABE 14F look for the photoelectric-like interaction in the XMASS detector assuming the hidden photon constitutes all the local dark matter. Limits between 2×10^{-13} and 1×10^{-12} are obtained, where the relation $\chi^2 = \alpha'/\alpha$ is used to translate the original bound on the ratio of the hidden and EM fine-structure constants. See their Fig. 3 for mass-dependent limits.

[111] AGAKISHIEV 14 look for hidden photons $\gamma' \to e^+e^-$ at the HADES experiment, and set limits on χ for $m_{\gamma'} = 0.02$–0.6 GeV. See their Fig. 5 for mass-dependent limits.

[112] BABUSCI 14 look for the decay $\gamma' \to \mu^+\mu^-$ in the reaction $e^+e^- \to \mu^+\mu^-\gamma$. Limits between 4×10^{-3} and 9.0×10^{-4} are obtained for 520 MeV $< m_{\gamma'} <$ 980 MeV (see their Fig. 7).

[113] BATELL 14 derived limits from the electron beam dump experiment at SLAC (E-137) by searching for events with recoil electrons by sub-GeV dark matter produced from the decay of the hidden photon. Limits at the level of 10^{-4}–10^{-1} are obtained for $m_{\gamma'} = 10^{-3}$–1 GeV, depending on the dark matter mass and the hidden gauge coupling (see their Fig. 2).

[114] BLUEMLEIN 14 analyzed the beam dump data taken at the U-70 accelerator to look for γ'-bremsstrahlung and the subsequent decay into muon pairs and hadrons. See their Fig. 4 for mass-dependent excluded region.

[115] FRADETTE 14 studied effects of decay of relic hidden photons on BBN and CMB to set constraints on very small values of the kinetic mixing. See their Figs. 4 and 7 for mass-dependent excluded regions.

[116] LEES 14J look for hidden photons in the reaction $e^+e^- \to \gamma\gamma'$ ($\gamma' \to e^+e^-, \mu^+\mu^-$). Limits at the level of 10^{-4}–10^{-3} are obtained for 0.02 GeV $< m_{\gamma'} <$ 10.2 GeV. See their Fig. 4 for mass-dependent limits.

[117] MERKEL 14 look for $\gamma' \to e^+e^-$ at the A1 experiment at the Mainz Microtron (MAMI). See their Fig. 3 for mass-dependent limits.

[118] AN 13B examined the stellar production of hidden photons, correcting an important error of the production rate of the longitudinal mode which now dominates. See their Fig. 2 for mass-dependent limits based on solar energy loss.

[119] AN 13C use the solar flux of hidden photons to set a limit on the atomic ionization rate in the XENON10 experiment. They find $\chi\, m_{\gamma'} < 3\times10^{-12}$ eV for $m_{\gamma'} < 1$ eV. See their Fig. 2 for mass-dependent limits.

[120] DIAMOND 13 analyzed the beam dump data taken at the SLAC millicharge experiment to constrain a hidden photon invisibly decaying into lighter long-lived particles, which undergo elastic scattering off nuclei in the detector. Limits between 8×10^{-4}–2×10^{-2} are obtained. The quoted limit is applied when the dark gauge coupling is set equal to the electromagnetic coupling. See their Fig.4 for mass-dependent limits.

[121] GNINENKO 13 used the data taken at the SINDRUM experiment to constrain the decay, $\pi^0 \to \gamma\gamma'$ ($\gamma' \to e^+e^-$) to derive limits. See their Fig. 2 for their mass-dependent excluded region.

[122] HORVAT 13 look for hidden-photo-electric effect in HPGe detectors induced by solar hidden photons. See their Fig. 3 for mass-dependent limits.

[123] INADA 13 search for hidden photons using an intense X-ray beamline at SPring-8. See their Fig. 4 for mass-dependent limits.

[124] MIZUMOTO 13 look for solar hidden photons. See their Fig. 5 for mass-dependent limits.

[125] PARKER 13 look for hidden photons using a cryogenic resonant microwave cavity. See their Fig.5 for mass-dependent limits.

[126] PARKER 13 derived a limit for the hidden photon CDM with a randomly oriented hidden photon field.

[127] REDONDO 13 examined the solar emission of hidden photons including the enhancement factor for the longitudinal mode pointed out by AN 13B, and also updated stellar-energy loss arguments. See their Fig.3 for mass-dependent limits, including a review of the currently best limits from other arguments.

[128] GNINENKO 12A obtained bounds on $B(\pi^0 \to \gamma\gamma') \cdot B(\gamma' \to e^+e^-)$ from the NOMAD and PS191 neutrino experiments, and derived limits between 8×10^{-8}–2×10^{-4}. See their Fig.4 for mass-dependent excluded regions.

[129] GNINENKO 12B used the data taken at the CHARM experiment to constrain the decay, $\eta(\eta') \to \gamma\gamma'$ ($\gamma' \to e^+e^-$), and derived limits between 1×10^{-7}–1×10^{-4}. See their Fig.4 for mass-dependent excluded region.

[130] ABRAHAMYAN 11 look for $\gamma' \to e^+e^-$ in the electron-nucelon fixed-target experiment at the Jefferson Laboratory (APEX). See their Fig. 5 for mass-dependent limits.

[131] BLUEMLEIN 11 analyzed the beam dump data taken at the U-70 accelerator to look for $\pi^0 \to \gamma\gamma'$ ($\gamma' \to e^+e^-$). See their Fig. 5 for mass-dependent limits.

[132] BJORKEN 09 analyzed the beam dump data taken at E137, E141, and E774 to constrain a hidden photon produced by bremsstrahlung, subsequently decaying into e^+e^-, and

derived limits between 10^{-7} and 10^{-2}. See their Fig. 1 for mass-dependent excluded region.

[133] BJORKEN 09 required the energy loss in the γ' emission from the core of SN1987A not to exceed 10^{53} erg/s, and derived limits between 5×10^{-9} and 2×10^{-6}. See their Fig. 1 for mass-dependent excluded region.

e MASS (atomic mass units u)

The primary determination of an electron's mass comes from measuring the ratio of the mass to that of a nucleus, so that the result is obtained in u (atomic mass units). The conversion factor to MeV is more uncertain than the mass of the electron in u; indeed, the recent improvements in the mass determination are not evident when the result is given in MeV. In this datablock we give the result in u, and in the following datablock in MeV.

VALUE (10^{-6} u)	DOCUMENT ID		TECN	COMMENT

[1] BEIER 02 compares Larmor frequency of the electron bound in a $^{12}C^{5+}$ ion with the cyclotron frequency of a single trapped $^{12}C^{5+}$ ion.
[2] FARNHAM 95 compares cyclotron frequency of trapped electrons with that of a single trapped $^{12}C^{6+}$ ion.

e MASS

The mass is known more precisely in u (atomic mass units) than in MeV. The conversion is: 1 u = 931.494 102 42(28) MeV/c^2 (2018 CODATA value, TIESINGA 21). The conversion error dominates the uncertainty of the masses given below.

[1] Converted to MeV using the 1998 CODATA value of the conversion constant, 931.494013 ± 0.000037 MeV/u.
[2] BEIER 02 compares Larmor frequency of the electron bound in a $^{12}C^{5+}$ ion with the cyclotron frequency of a single trapped $^{12}C^{5+}$ ion.
[3] FARNHAM 95 compares cyclotron frequency of trapped electrons with that of a single trapped $^{12}C^{6+}$ ion.

$(m_{e^+} - m_{e^-}) / m_{average}$

A test of CPT invariance.

VALUE	CL%	DOCUMENT ID		TECN	COMMENT
$<8\times10^{-9}$	90	[1] FEE	93	CNTR	Positronium spectroscopy
• • • We do not use the following data for averages, fits, limits, etc. • • •					
$<4\times10^{-23}$	90	[2] DOLGOV	14		From photon mass limit
$<4\times10^{-8}$	90	CHU	84	CNTR	Positronium spectroscopy

[1] FEE 93 value is obtained under the assumption that the positronium Rydberg constant is exactly half the hydrogen one.
[2] DOLGOV 14 result is obtained under the assumption that any mass difference between electron and positron would lead to a non-zero photon mass. The PDG 12 limit of 1×10^{-18} eV on the photon mass is in turn used to derive the value quoted here.

$|q_{e^+} + q_{e^-}|/e$

A test of CPT invariance. See also similar tests involving the proton.

$<4\times10^{-8}$	[1] HUGHES	92	RVUE	
• • • We do not use the following data for averages, fits, limits, etc. • • •				
$<2\times10^{-18}$	[2] SCHAEFER	95	THEO	Vacuum polarization
$<1\times10^{-18}$	[3] MUELLER	92	THEO	Vacuum polarization

[1] HUGHES 92 uses recent measurements of Rydberg-energy and cyclotron-frequency ratios.
[2] SCHAEFER 95 removes model dependency of MUELLER 92.
[3] MUELLER 92 argues that an inequality of the charge magnitudes would, through higher-order vacuum polarization, contribute to the net charge of atoms.

[1] FAN 23 report the most accurate measurement of the electron magnetic moment. A one-electron quantum cyclotron is used. We do not propagate at the moment this measurement to the fine structure and other physical constants. When discrepancies in the independent determinations of alpha are resolved, the new measurement uncertainty of 0.13 ppt is available for precise tests for BSM physics.
[2] MOHR 08 average is dominated by ODOM 06.
[3] Superseded by HANNEKE 08 per private communication with Gerald Gabrielse.
[4] This VANDYCK 87 reault is for a positron. We do not take it into account for the average to avoid the assumption of CPT invariance.

$(g_{e^+} - g_{e^-}) / g_{average}$

A test of CPT invariance.

[7] ABDULLAH 90, COMMINS 94, and REGAN 02 use the relativistic enhancement of a valence electron's electric dipole moment in a high-Z atom.

e^- MEAN LIFE / BRANCHING FRACTION

A test of charge conservation. See the "Note on Testing Charge Conservation and the Pauli Exclusion Principle" following this section in our 1992 edition (Physical Review **D45** S1 (1992), p. VI.10).

Most of these experiments are one of three kinds: Attempts to observe (a) the 255.5 keV gamma ray produced in $e^- \to \nu_e \gamma$, (b) the (K) shell x ray produced when an electron decays without additional energy deposit, e.g., $e^- \to \nu_e \overline{\nu}_e \nu_e$ ("disappearance" experiments), and (c) nuclear de-excitation gamma rays after the electron disappears from an atomic shell and the nucleus is left in an excited state. The last can include both weak boson and photon mediating processes. We use the best $e^- \to \nu_e \gamma$ limit for the Summary Tables.

Note that we use the mean life rather than the half life, which is often reported.

μ

$J = \frac{1}{2}$

μ MASS (atomic mass units u)

The muon's mass is obtained from the muon-electron mass ratio as determined from the measurement of Zeeman transition frequencies in muonium ($\mu^+ e^-$ atom). Since the electron's mass is most accurately known in u, the muon's mass is also most accurately known in u. The conversion factor to MeV has approximately the same relative uncertainty as the mass of the muon in u. In this datablock we give the result in u, and in the following datablock in MeV.

[2] COHEN 87 make use of other 1986 CODATA entries below.

μ MASS

The mass is known more precisely in u (atomic mass units) than in MeV. The conversion is: 1 u = 931.494 102 42(28) MeV/c^2 (2018 CODATA value, TIESINGA 21). The conversion error contributes significantly to the uncertainty of the masses given below.

μ/p MAGNETIC MOMENT RATIO

This ratio is used to obtain a precise value of the muon mass and to reduce experimental muon Larmor frequency measurements to the muon magnetic moment anomaly. Measurements with an error > 0.00001 have been omitted. By convention, the minus sign on this ratio is omitted. CODATA values were fitted using their selection of data, plus other data from multiparameter fits.

Muon Anomalous Magnetic Moment

μ MAGNETIC MOMENT ANOMALY

The parity-violating decay of muons in a storage ring is observed. The difference frequency ω_a between the muon spin precision and the orbital angular frequency $(e/m_\mu c)\langle B \rangle$ is measured, as is the free proton NMR frequency ω_p, thus determining the ratio $R=\omega_a/\omega_p$. Given the magnetic moment ratio $\lambda=\mu_\mu/\mu_p$ (from hyperfine structure in muonium), $(g-2)/2 = R/(\lambda-R)$.

$\mu_\mu/(e\hbar/2m_\mu)-1 = (g_\mu-2)/2$

[1] AGUILLARD 23 combined their value with the previous independent BNL measurement of BENNETT 06.
[2] This AGUILLARD 23 value is the combination of all 2018, 2019 and 2020 data, including the ABI 21 value. The new FNAL 2019 and 2020 data alone combined yield $(11659205.7 \pm 2.5) \times 10^{-10}$.
[3] ABI 21 combined their value with the previous independent BNL measurement of BENNETT 06. ABI 21 also report that the difference of this combination with the standard model value of $(11659181.0 \pm 4.3) \times 10^{-10}$ (AOYAMA 20) has a significance of 4.2 σ.
[4] BAILEY 79 values recalculated by HUGHES 99 using the COHEN 87 μ/p magnetic moment. The improved MOHR 99 value does not change the result.

$(g_{\mu^+} - g_{\mu^-}) / g_{\text{average}}$

A test of CPT invariance.

[1] This is the combination of the two BENNETT 09 measurements quoted here separately for μ^+ and μ^-. The result is also presented as a measurement of $(0.0 \pm 0.9) \times 10^{-19}$ e cm.
[2] EMA 22 determine indirect constraints on $|\mu_{EDM}|$ from EDM measurements performed on heavy atoms and molecules, based on the muon-loop induced light-by-light CP-odd amplitude.
[3] Also reported as the limit of $|\mathrm{d}(\mu^+)| < 2.1 \times 10^{-19}$ e cm at 95% CL.
[4] Also reported as the limit of $|\mathrm{d}(\mu^-)| < 1.5 \times 10^{-19}$ e cm at 95% CL.
[5] This is the combination of the two BAILEY 78 results quoted here separately for μ^+ and μ^-. BAILEY 78 uses the convention $\mathrm{d} = 1/2 \cdot (\mathrm{d}_{\mu^+} - \mathrm{d}_{\mu^-})$ and reports 3.7 ± 3.4. We convert their result to use the same convention as BENNETT 09.

MUON-ELECTRON CHARGE RATIO ANOMALY $q_{\mu^+}/q_{e^-} + 1$

VALUE	DOCUMENT ID		TECN	CHG	COMMENT
(1.1±2.1) × 10^{-9}	[1] MEYER	00	CNTR	+	1s–2s muonium interval

[1] MEYER 00 measure the 1s–2s muonium interval, and then interpret the result in terms of muon-electron charge ratio q_{μ^+}/q_{e^-}.

μ^- DECAY MODES

μ^+ modes are charge conjugates of the modes below.

	Mode		Fraction (Γ_i/Γ)		Confidence level
Γ_1	$e^- \overline{\nu}_e \nu_\mu$		≈ 100%		
Γ_2	$e^- \overline{\nu}_e \nu_\mu \gamma$	[a]	$(6.0 \pm 0.5) \times 10^{-8}$		
Γ_3	$e^- \overline{\nu}_e \nu_\mu e^+ e^-$	[b]	$(3.4 \pm 0.4) \times 10^{-5}$		
	Lepton Family number (LF) violating modes				
Γ_4	$e^- \nu_e \overline{\nu}_\mu$	LF [c]	< 1.2	%	90%
Γ_5	$e^- \gamma$	LF	< 4.2	$\times 10^{-13}$	90%
Γ_6	$e^- e^+ e^-$	LF	< 1.0	$\times 10^{-12}$	90%
Γ_7	$e^- 2\gamma$	LF	< 7.2	$\times 10^{-11}$	90%

[a] This only includes events with energy of $e > 45$ MeV and energy of $\gamma > 40$ MeV. Since the $e^- \overline{\nu}_e \nu_\mu$ and $e^- \overline{\nu}_e \nu_\mu \gamma$ modes cannot be clearly separated, we regard the latter mode as a subset of the former.
[b] See the Particle Listings below for the energy limits used in this measurement.
[c] A test of additive vs. multiplicative lepton family number conservation.

μ^- BRANCHING RATIOS

[1] This limit assumes a giant resonance excitation of the daughter Ca nucleus (mean energy and width both 20 MeV).
[2] KAULARD 98 obtained these same limits using the unified classical analysis of FELDMAN 98.
[3] This limit assumes the daughter Ca nucleus is left in the ground state. However, the probability of this is unknown.
[4] Assuming a giant-resonance-excitation model.

LIMIT ON MUONIUM → ANTIMUONIUM CONVERSION

Forbidden by lepton family number conservation.

$R_g = G_C / G_F$

The effective Lagrangian for the $\mu^+ e^- \to \mu^- e^+$ conversion is assumed to be

$$\mathcal{L} = 2^{-1/2}\, G_C\, [\overline{\psi}_\mu \gamma_\lambda\, (1-\gamma_5)\, \psi_e]\, [\overline{\psi}_\mu \gamma_\lambda\, (1-\gamma_5)\, \psi_e] + \text{h.c.}$$

The experimental result is then an upper limit on G_C/G_F, where G_F is the Fermi coupling constant.

0.93 ±0.06	PLANO	60	HBC	+	8.8 kG
0.97 ±0.05	BARDON	59	CNTR		Bromoform target

[1] The corresponding 90% confidence limit from IMAZATO 92 is $|\xi P_\mu| > 0.990$. This measurement is of K^+ decay, not π^+ decay, so we do not include it in an average, nor do we yet set up a separate data block for K results.

[2] Depolarization by medium not known sufficiently well.

$\xi \times (\mu$ LONGITUDINAL POLARIZATION$) \times \delta / \rho$

VALUE	CL%	DOCUMENT ID		TECN	CHG	COMMENT
1.00179 $^{+0.00156}_{-0.00071}$		[1] BAYES	11	TWST	+	Surface μ^+ beam

>0.99682	90	[2] JODIDIO	86	SPEC	+	TRIUMF
>0.9966	90	[3] STOKER	85	SPEC	+	μ-spin rotation
>0.9959	90	CARR	83	SPEC	+	11 kG

[1] BAYES 11 obtains the limit > 0.99909 (90% CL) with the constraint that $\xi\times(\mu$ LONGITUDINAL POLARIZATION$) \times \delta/\rho \leq 1.0$.

[2] JODIDIO 86 includes data from CARR 83 and STOKER 85. The value here is from the erratum.

[3] STOKER 85 find $(\xi P_\mu \delta/\rho) > 0.9955$ and > 0.9966, where the first limit is from new μ spin-rotation data and the second is from combination with CARR 83 data. In $V-A$ theory, $(\delta/\rho) = 1.0$.

ξ' = LONGITUDINAL POLARIZATION OF e^+

($V-A$) theory predicts the longitudinal polarization = ± 1 for $e^\pm$, respectively. We have flipped the sign for e^- so our programs can average.

τ

$J = \frac{1}{2}$

τ discovery paper was PERL 75. $e^+e^- \to \tau^+\tau^-$ cross-section threshold behavior and magnitude are consistent with pointlike spin-1/2 Dirac particle. BRANDELIK 78 ruled out pointlike spin-0 or spin-1 particle. FELDMAN 78 ruled out $J = 3/2$. KIRKBY 79 also ruled out J=integer, $J = 3/2$.

[1] ADACHI 23C, AUBERT 09AK and BELOUS 07 fit τ pseudomass spectrum in $\tau \to \pi\pi^+\pi^-\nu_\tau$ decays. Result assumes $m_{\nu_\tau} = 0$.

[2] Previously also reported LEVICHEV 14. Superseedes ANASHIN 07.

[3] ABLIKIM 14D fit $\sigma(e^+e^- \to \tau^+\tau^-)$ at different energies near threshold.

[4] ABBIENDI 00A fit τ pseudomass spectrum in $\tau \to \pi^\pm \leq 2\pi^0\nu_\tau$ and $\tau \to \pi^\pm\pi^+\pi^- \leq 1\pi^0\nu_\tau$ decays. Result assumes m_{ν_τ}=0.

[5] BAI 96 fit $\sigma(e^+e^- \to \tau^+\tau^-)$ at different energies near threshold.

[6] ALBRECHT 92M fit τ pseudomass spectrum in $\tau^- \to 2\pi^-\pi^+\nu_\tau$ decays. Result assumes m_{ν_τ}=0.

[7] BACINO 78B value comes from $e^\pm X^\mp$ threshold. Published mass 1782 MeV increased by 1 MeV using the high precision $\psi(2S)$ mass measurement of ZHOLENTZ 80 to eliminate the absolute SPEAR energy calibration uncertainty.

[8] BALEST 93 fit spectra of minimum kinematically allowed τ mass in events of the type $e^+e^- \to \tau^+\tau^- \to (\pi^+ n\pi^0\nu_\tau)(\pi^- m\pi^0\nu_\tau)$ $n \leq 2$, $m \leq 2$, $1 \leq n+m \leq 3$. If $m_{\nu_\tau} \neq 0$, result increases by $(m^2_{\nu_\tau}/1100$ MeV).

[9] BAI 92 fit $\sigma(e^+e^- \to \tau^+\tau^-)$ near threshold using $e\mu$ events.

$(m_{\tau^+} - m_{\tau^-})/m_{\text{average}}$

A test of CPT invariance.

< 0.023	95	[11] SILVERMAN	83	RVUE	$e^+e^- \to \tau^+\tau^-$ at PETRA

[1] AAD 23BM measurement is derived from $\gamma\gamma \to \tau^+\tau^-$ total cross-section from 1.44 nb^{-1} LHC Pb-Pb collisions at $\sqrt{s_{NN}} = 5.02$ TeV. Authors report both the measured value and the corresponding 95% CL limit.

[2] Measurement ill-suited for a standard average because its likelihood appears to be remarkably non-Gaussian and asymmetric according to the model-dependent extraction procedure and the reported 95% CL limits.
[3] TUMASYAN 23AS measurement is derived from $\gamma\gamma \to \tau^+\tau^-$ total cross-section from 404 μb^{-1} LHC Pb-Pb collisions at $\sqrt{s_{NN}} = 5.02$ TeV.
[4] ABDALLAH 04K measurement is derived from $e^+e^- \to e^+e^-\tau^+\tau^-$ total cross-section measurements at $\sqrt{s}$ between 183 and 208 GeV. In addition to the measurement, the authors also quote 95% CL limits of > -0.052 and < 0.013.
[5] ACHARD 04G limit is derived from $e^+e^- \to e^+e^-\tau^+\tau^-$ total cross-section measurements at $\sqrt{s}$ between 189 and 206 GeV, and is on the absolute value of the magnetic moment anomaly.
[6] GONZALEZ-SPRINBERG 00 use data on tau lepton production at LEP1, SLC, and LEP2, and data from colliders and LEP2 to determine limits. Assume imaginary component is zero.
[7] ACCIARRI 98E use $Z \to \tau^+\tau^-\gamma$ events. In addition to the limits, the authors also quote a value of $0.004 \pm 0.027 \pm 0.023$.
[8] ACKERSTAFF 98N use $Z \to \tau^+\tau^-\gamma$ events. The limit applies to an average of the form factor for off-shell τ's having p^2 ranging from m_τ^2 to $(M_Z - m_\tau)^2$.
[9] ESCRIBANO 97 use preliminary experimental results.
[10] ESCRIBANO 93 limit derived from $\Gamma(Z \to \tau^+\tau^-)$, and is on the absolute value of the magnetic moment anomaly.
[11] SILVERMAN 83 limit is derived from $e^+e^- \to \tau^+\tau^-$ total cross-section measurements for q^2 up to (37 GeV)^2.

τ ELECTRIC DIPOLE MOMENT (d_τ)

A nonzero value is forbidden by both T invariance and P invariance.

The q^2 dependence is expected to be small providing no thresholds are nearby.

Lepton Family number (LF), Lepton number (L), or Baryon number (B) violating modes

L means lepton number violation (*e.g.* $\tau^- \to e^+\pi^-\pi^-$). Following common usage, LF means lepton family violation *and not* lepton number violation (*e.g.* $\tau^- \to e^-\pi^+\pi^-$). B means baryon number violation.

Γ_{186}	$e^-\gamma$	LF	< 3.3		$\times 10^{-8}$	CL=90%
Γ_{187}	$e^-\gamma\gamma$	LF	< 2.5		$\times 10^{-4}$	CL=90%

[b] See the Particle Listings below for the energy limits used in this measurement.

CONSTRAINED FIT INFORMATION

An overall fit to 85 branching ratios uses 170 measurements and one constraint to determine 46 parameters. The overall fit has a $\chi^2 = 135.0$ for 125 degrees of freedom.

The following *off-diagonal* array elements are the correlation coefficients $\left\langle \delta x_i \delta x_j \right\rangle / (\delta x_i \cdot \delta x_j)$, in percent, from the fit to the branching fractions, $x_i \equiv \Gamma_i / \Gamma_{\text{total}}$. The fit constrains the x_i whose labels appear in this array to sum to one.

$\Gamma_1/\Gamma = (\Gamma_3+\Gamma_5+\Gamma_9+\Gamma_{10}+\Gamma_{14}+\Gamma_{16}+\Gamma_{20}+\Gamma_{23}+\Gamma_{27}+\Gamma_{28}+\Gamma_{30}+\Gamma_{36}+\Gamma_{38}+\Gamma_{41}+\Gamma_{43}+\Gamma_{45}+\Gamma_{48}+\Gamma_{49}+\Gamma_{52}+\Gamma_{56}+\Gamma_{57}+0.7196\Gamma_{150}+0.7196\Gamma_{152}+0.7196\Gamma_{154}+0.7196\Gamma_{156}+0.339\Gamma_{170}+0.0835\Gamma_{178}+0.0835\Gamma_{179}+0.0835\Gamma_{180})/\Gamma$

The charged particle here can be e, μ, or hadron. In many analyses, the sum of the topological branching fractions (1, 3, and 5 prongs) is constrained to be unity. Since the 5-prong fraction is very small, the measured 1-prong and 3-prong fractions are highly correlated and cannot be treated as independent quantities in our overall fit. We arbitrarily choose to use the 3-prong fraction in our fit, and leave the 1-prong fraction out. We do, however, use these 1-prong measurements in our average below.

[1] Combined fit to ARGUS tau decay parameter measurements in ALBRECHT 98, ALBRECHT 95C, ALBRECHT 93G, and ALBRECHT 94E. ALBRECHT 98 use tau pair events of the type $\tau^-\tau^+\to(\ell^-\overline{\nu}_\ell\nu_\tau)(\pi^+\pi^0\overline{\nu}_\tau)$, and their charged conjugates.
[2] ABE 97O assume $\eta = 0$ in their fit. Letting η vary in the fit gives a ρ value of 0.69 ± 0.13 ± 0.05.
[3] Value is from a simultaneous fit for the ρ and η decay parameters to the lepton energy spectrum. Not independent of ALBRECHT 90E $\rho(e$ or $\mu)$ value which assumes $\eta = 0$. Result is strongly correlated with ALBRECHT 95C.
[4] Combined fit to ARGUS tau decay parameter measurements in ALBRECHT 95C, ALBRECHT 93G, and ALBRECHT 94E.

1.14 ±0.34 $^{+0.34}_{-0.17}$	3.9k	[9] ALBRECHT	90I	ARG	Repl. by ALBRECHT 93C

[1] HEISTER 01E quote 0.992 ± 0.007 ± 0.006 ± 0.005 where the errors are statistical, systematic, and an uncertainty due to the final state model. We combine the systematic error and model uncertainty. They use $\tau \to \pi\nu_\tau$, $\tau \to K\nu_\tau$, $\tau \to \rho\nu_\tau$, and $\tau \to a_1\nu_\tau$ decays.
[2] ABREU 00L use $\tau^- \to h^- \geq 0\pi^0\nu_\tau$ decays.
[3] ASNER 00 use $\tau^- \to \pi^- 2\pi^0\nu_\tau$ decays.
[4] ACCIARRI 98R use $\tau \to \pi\nu_\tau$, $\tau \to K\nu_\tau$, and $\tau \to \rho\nu_\tau$ decays.
[5] ACKERSTAFF 97R use $\tau \to a_1\nu_\tau$ decays.
[6] ALEXANDER 97F use $\tau \to \rho\nu_\tau$ decays.
[7] COAN 97 use h^+h^- energy correlations.
[8] Combined fit to ARGUS tau decay parameter measurements in ALBRECHT 95C, ALBRECHT 93G, and ALBRECHT 94E.
[9] Uses $\tau \to a_1\nu_\tau$ decays. Replaced by ALBRECHT 95C.
[10] ACCIARRI 96H use $\tau \to \pi\nu_\tau$, $\tau \to K\nu_\tau$, and $\tau \to \rho\nu_\tau$ decays.
[11] AKERS 95P use $\tau \to a_1\nu_\tau$ decays.
[12] BUSKULIC 95D use $\tau \to \pi\nu_\tau$, $\tau \to \rho\nu_\tau$, and $\tau \to a_1\nu_\tau$ decays.
[13] ALBRECHT 94E measure the square of this quantity and use the sign determined by ALBRECHT 90I to obtain the quoted result. Uses $\tau \to a_1\nu_\tau$ decays. Replaced by ALBRECHT 95C.
[14] BUSKULIC 94D use $\tau \to \pi\nu_\tau$ and $\tau \to \rho\nu_\tau$ decays. Superseded by BUSKULIC 95D.

$\xi'(\mu)$ PARAMETER

($V-A$) theory predicts $\xi' = 1$.

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
0.22±0.94±0.42	165	BODROV	23	BELL	$E_{\rm cm}^{ee}$ = 10.6 GeV

$\overline{\eta}(\mu)$ PARAMETER

($V-A$) theory predicts $\overline{\eta}(\mu) = 0$.

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
−1.3±1.5±0.8	71k	[1] SHIMIZU	18A	BELL	$\tau^- \to \nu_\tau\mu^-\overline{\nu}_\mu\gamma$

[1] SHIMIZU 18A measurement procedure fits a distribution affected by $\overline{\eta}(\mu)$, $\xi\kappa(\mu)$ and $\eta''(\mu)$, floating $\overline{\eta}(\mu)$ and $\xi\kappa(\mu)$ and fixing $\eta''(\mu) = 0$. The contribution of $\eta''(\mu)$ is suppressed by m_μ/m_τ.

$(\xi\kappa)(e$ or $\mu)$ PARAMETER

($V-A$) theory predicts $(\xi\kappa)(e$ or $\mu) = 0$.

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
0.5±0.4±0.2	149k	[1,2] SHIMIZU	18A	BELL	$\tau^- \to \nu_\tau e^-\overline{\nu}_e\gamma$ and $\tau^- \to \nu_\tau\mu^-\overline{\nu}_\mu\gamma$

[1] SHIMIZU 18A measurement procedure fits a distribution of radiative tau decays into both electrons and muons affected by $\overline{\eta}(e$ or $\mu)$, $\xi\kappa(e$ or $\mu)$ and $\eta''(e$ or $\mu)$, floating $\overline{\eta}(e$ or $\mu)$ and $\xi\kappa(e$ or $\mu)$ and fixing $\eta''(e$ or $\mu) = 0$. The contribution of $\eta''(e$ or $\mu)$ is suppressed by m_e/m_τ for tau decaying to electrons and by m_μ/m_τ for tau decaying to muons.
[2] Error correlated with SHIMIZU 18A $(\xi\kappa)(e)$ and $(\xi\kappa)(\mu)$ values.

$(\xi\kappa)(e)$ PARAMETER

($V-A$) theory predicts $(\xi\kappa)(e) = 0$.

VALUE	EVTS	DOCUMENT ID		TECN	COMMENT
−0.4±0.8±0.9	78k	[1,2] SHIMIZU	18A	BELL	$\tau^- \to \nu_\tau e^-\overline{\nu}_e\gamma$

[1] SHIMIZU 18A measurement procedure fits a distribution affected by $\overline{\eta}(e)$, $(\xi\kappa)(e)$ and $\eta''(e)$, floating $(\xi\kappa)(e)$ and fixing $\overline{\eta}(e) = 0$ and $\eta''(e) = 0$. The contribution of $\eta''(e)$ is suppressed by m_e/m_τ.
[2] Error correlated with SHIMIZU 18A $(\xi\kappa)(e$ or $\mu)$ value.

$(\xi\kappa)(\mu)$ PARAMETER

($V-A$) theory predicts $(\xi\kappa)(\mu) = 0$.

Heavy Charged Lepton Searches

Charged Heavy Lepton MASS LIMITS

Sequential Charged Heavy Lepton ($L^{\pm}$) MASS LIMITS

These experiments assumed that a fourth generation $L^{\pm}$ decayed to a fourth generation ν_L (or L^0) where ν_L was stable, or that $L^{\pm}$ decays to a light ν_ℓ via mixing.

See the "Quark and Lepton Compositeness, Searches for" Listings for limits on radiatively decaying excited leptons, *i.e.* $\ell^* \to \ell\gamma$. See the "WIMPs and other Particle Searches" section for heavy charged particle search limits in which the charged particle could be a lepton.

[1] ACCIARRI 96G assumes LEP result that the associated neutral heavy lepton mass > 40 GeV.

[2] The AHMED 94 limits are from a search for neutral and charged sequential heavy leptons at HERA via the decay channels $L^- \to e\gamma$, $L^- \to \nu W^-$, $L^- \to eZ$; and $L^0 \to \nu\gamma$, $L^0 \to e^- W^+$, $L^- \to \nu Z$, where the W decays to $\ell\nu_\ell$, or to jets, and Z decays to $\ell^+\ell^-$ or jets.

[3] RILES 90 limits were the result of a special analysis of the data in the case where the mass difference $m_{L^-} - m_{L^0}$ was allowed to be quite small, where L^0 denotes the neutrino into which the sequential charged lepton decays. With a slightly reduced $m_{L^\pm}$ range, the mass difference extends to about 4 GeV.

[4] STOKER 89 (Mark II at PEP) gives bounds on charged heavy lepton (L^+) mass for the generalized case in which the corresponding neutral heavy lepton (L^0) in the SU(2) doublet is not of negligible mass.

[5] ABE 88 search for L^+ and $L^- \to$ hadrons looking for acoplanar jets. The bound is valid for $m_\nu < 10$ GeV.

[6] ADACHI 88B search for hadronic decays giving acoplanar events with large missing energy. $E_{cm}^{ee} = 52$ GeV.

[7] Assumes associated neutrino is approximately massless.

[8] ADEVA 85 analyze one-isolated-muon data and sensitive to τ <10 nanosec. Assume B(lepton) = 0.30. $E_{cm} = 40$–47 GeV.

[9] BARTEL 83 limit is from PETRA e^+e^- experiment with average $E_{cm} = 34.2$ GeV.

[10] BERGER 81B is DESY DORIS and PETRA experiment. Looking for $e^+e^- \to L^+L^-$.

[11] BRANDELIK 81 is DESY-PETRA experiment. Looking for $e^+e^- \to L^+L^-$.

[12] AZIMOV 80 estimated probabilities for $M + N$ type events in $e^+e^- \to L^+L^-$ deducing semi-hadronic decay multiplicities of L from e^+e^- annihilation data at $E_{cm} = (2/3)m_L$. Obtained above limit comparing these with e^+e^- data (BRANDELIK 80).

[13] BARBER 80B looked for $e^+e^- \to L^+L^-$, $L \to \nu_L^+ X$ with MARK-J at DESY-PETRA.

[14] ROTHE 69 examines previous data on μ pair production and π and K decays.

Stable Charged Heavy Lepton ($L^{\pm}$) MASS LIMITS

Neutrino Properties

NEUTRINO PROPERTIES

Revised July 2023 by P. Vogel (Caltech) and A. Piepke (University of Alabama).

The Neutrino Properties Listings concern measurements of various properties of neutrinos. Nearly all of the measurements, so far only limits, actually concern superpositions of the mass eigenstates ν_i, which are in turn related to the weak eigenstates ν_ℓ, via the neutrino mixing matrix

$$|\nu_\ell\rangle = \sum_i U_{\ell i}\,|\nu_i\rangle \ .$$

In the analogous case of quark mixing via the CKM matrix, the smallness of the off-diagonal terms (small mixing angles) permits a "dominant eigenstate" approximation. However, the results of neutrino oscillation searches show that the mixing matrix contains two large mixing angles and a third angle that is not exceedingly small. We cannot therefore associate any particular state $|\nu_i\rangle$ with any particular lepton label e, μ or τ. Nevertheless, note that in the standard labeling the $|\nu_1\rangle$ has the largest $|\nu_e\rangle$ component ($\sim 2/3$), $|\nu_2\rangle$ contains $\sim 1/3$ of the $|\nu_e\rangle$ component and $|\nu_3\rangle$ contains only a small $\sim 2.5\%$ $|\nu_e\rangle$ component.

Neutrinos are produced in weak decays with a definite lepton flavor, and are typically detected by the charged current weak interaction again associated with a specific lepton flavor. Hence, the listings for the neutrino mass that follow are separated into the three associated charged lepton categories. Other properties (mean lifetime, magnetic moment, charge and charge radius) are no longer separated this way. If needed, the associated lepton flavor is reported in the footnotes.

Measured quantities (mass-squared, magnetic moments, mean lifetimes, *etc.*) all depend upon the mixing parameters $|U_{\ell i}|^2$, but to some extent also on experimental conditions (e.g., on energy resolution). Many of these observables, in particular mass-squared, cannot distinguish between Dirac and Majorana neutrinos and are unaffected by CP phases.

Direct neutrino mass measurements are usually based on the analysis of the kinematics of charged particles (leptons, pions) emitted together with neutrinos (flavor states) in various weak decays. The most sensitive neutrino mass measurement to date, involving electron type antineutrinos, is based on fitting the shape of the beta spectrum. The quantity $m^{2(eff)}_{\nu_e} = \sum_i |U_{ei}|^2 m^2_{\nu_i}$ is determined or constrained, where the sum is over all mass eigenvalues m_{ν_i} that are too close together to be resolved experimentally. (The quantity $m^{eff}_{\nu_e} \equiv \sqrt{m^{2(eff)}_{\nu_e}}$ is often denoted $\langle m_\beta \rangle$ in the literature.) If the energy resolution is better than $\Delta m^2_{ij} \equiv m^2_{\nu_i} - m^2_{\nu_j}$, the corresponding heavier m_{ν_i} and mixing parameter could be determined by fitting the resulting spectral anomaly (step or kink).

The dependence of m_{ν_e} on the mass of the lightest neutrino is shown in Fig. 14.11 of the *Neutrino Masses, Mixing, and Oscillations* review. In the case of inverted ordering there is a minimum possible value of $m^{eff}_{\nu_e}$, approximately $\sqrt{(}\Delta m^2_{32}) \sim 50$ meV. If $m^{eff}_{\nu_e}$ is found to be larger than this value, it is impossible, based on this information only, to decide which ordering is realized in nature. On the other hand, if the $m^{eff}_{\nu_e}$ is less than ~50 meV, only the normal mass ordering is possible.

A limit on $m^{2(eff)}_{\nu_e}$ implies an upper limit on the minimum value m^2_{min} of $m^2_{\nu_i}$, independent of the mixing parameters U_{ei}: $m^2_{min} \leq m^{2(eff)}_{\nu_e}$. However, if and when the value of $m^{2(eff)}_{\nu_e}$ is determined then its combination with the results derived from neutrino oscillations that give us the values of the neutrino mass-squared differences $\Delta m^2_{ij} \equiv m^2_i - m^2_j$, including eventually also their signs, and the mixing parameters $|U_{ei}|^2$, the individual neutrino mass squares $m^2_{\nu_j} = m^{2(eff)}_{\nu_e} - \sum_i |U_{ei}|^2 \Delta m^2_{ij}$ can be determined.

So far solar, reactor, atmospheric and accelerator neutrino oscillation experiments can be consistently described using three active neutrino flavors, i.e. two mass splittings and three mixing angles. However, several experiments with radioactive sources, reactors, and accelerators imply the possible existence of one or more non-interacting, i.e. sterile, neutrino species that might be observable since they couple, albeit weakly, to the flavor neutrinos $|\nu_l\rangle$. In that case, the neutrino mixing matrix would be $n \times n$ unitary matrix with $n > 3$.

Combined three neutrino analyses determine the squared mass differences and all three mixing angles to within reasonable accuracy. For given $|\Delta m^2_{ij}|$ a limit on $m^{2(eff)}_{\nu_e}$ from beta decay defines an upper limit on the maximum value m_{max} of m_{ν_i}: $m^2_{max} \leq m^{2(eff)}_{\nu_e} + \sum_{i<j} |\Delta m^2_{ij}|$. The analysis of the low energy

beta decay of tritium, combined with the oscillation results, thus limits *all* active neutrino masses. Traditionally, experimental neutrino mass limits obtained from pion decay $\pi^+ \to \mu^+ + \nu_\mu$ or the shape of the spectrum of decay products of the τ lepton did not distinguish between flavor and mass eigenstates. These results are reported as limits of the μ and τ based neutrino mass. After the determination of the $|\Delta m^2_{ij}|$'s and the mixing angles θ_{ij}, the corresponding neutrino mass limits are no longer competitive with those derived from low energy beta decays.

The spread of arrival times of the neutrinos from SN1987A, coupled with the measured neutrino energies, provided a time-of-flight limit on a quantity similar to $\langle m_\beta \rangle \equiv \sqrt{m^{2(eff)}_{\nu_e}}$. This statement, clothed in various degrees of sophistication, has been the basis for a very large number of papers. The resulting limits, however, are no longer comparable with the limits from tritium beta decay.

Constraint, or eventually a value, of the sum of the neutrino masses m_{tot} can be determined from the analysis of the cosmic microwave background anisotropy, combined with the galaxy redshift surveys and other data. These limits are reported in a separate table (Sum of Neutrino Masses, m_{tot}). Obviously, m_{tot} represents an upper limit for all m_i values. Note that many reported m_{tot} limits are considerably more stringent than the listed $m^{eff}_{\nu_e}$ limits. Discussion concerning the model dependence of the m_{tot} limit is continuing.

$\overline{\nu}$ MASS (electron based)

Those limits given below are for the square root of $m^{2(\text{eff})}_{\nu_e} \equiv \sum_i |U_{ei}|^2\ m^2_{\nu_i}$. Limits that come from the kinematics of $^3\text{H}\,\beta^-\overline{\nu}$ decay are the square roots of the limits for $m^{2(\text{eff})}_{\nu_e}$. Obtained from the measurements reported in the Listings for "$\overline{\nu}$ Mass Squared," below.

[1] AKER 22 derive an upper limit on the kinematical neutrino mass using Tritium β-decay and the KATRIN spectrometer. The constraint is based on combining the first two science runs. Supersedes AKER 19.

[2] ESFAHANI 23 report the first continuous-spectrum measurement of ^{3}H β decay, using cyclotron radiation emission spectroscopy (CRES) and a small demonstration detector. The energy resolution at the endpoint is demonstrated using ^{83m}Kr and a kinematical neutrino mass limit derived from the spectral shape. A frequentist analysis obtained a limit of <152 eV.

[3] AKER 19 report a neutrino mass limit, derived from the first month of data collected by the KATRIN tritium endpoint experiment. The analysis of the electron kinematics shows no evidence for neutrino mass. The quoted result is based on a frequentist analysis of the data following the method described in LOKHOV 15. Using the method of Feldman and Cousins, the derived upper limit is < 0.8 eV at 90% C.L. Superseded by AKER 22.

[4] ASEEV 11 report the analysis of the entire beta endpoint data, taken with the Troitsk integrating electrostatic spectrometer between 1997 and 2002 (some of the earlier runs were rejected), using a windowless gaseous tritium source. The fitted value of m_ν, based on the method of Feldman and Cousins, is obtained from the upper limit of the fit for m^2_ν. Previous analysis problems were resolved by careful monitoring of the tritium gas column density. Supersedes LOBASHEV 99 and BELESEV 95.

[5] PAGLIAROLI 10 is critical of the likelihood method used by LOREDO 02.

[6] KRAUS 05 is a continuation of the work reported in WEINHEIMER 99. This result represents the final analysis of data taken from 1997 to 2001. Various sources of systematic uncertainties have been identified and quantified. The background has been reduced compared to the initial running period. A spectral anomaly at the endpoint, reported in LOBASHEV 99, was not observed.

[7] ARNABOLDI 03A *et al.* report kinematical neutrino mass limit using β-decay of ^{187}Re. Bolometric $AgReO_4$ micro-calorimeters are used. Mass bound is substantially weaker than those derived from tritium β-decays but has different systematic uncertainties.

[8] LOREDO 02 updates LOREDO 89.

[9] LOBASHEV 99 report a new measurement which continues the work reported in BELESEV 95. This limit depends on phenomenological fit parameters used to derive their best fit to m^2_ν, making unambiguous interpretation difficult. See the footnote under "$\overline{\nu}$ Mass Squared."

[10] WEINHEIMER 99 presents two analyses which exclude the spectral anomaly and result in an acceptable m^2_ν. We report the most conservative limit, but the other is nearly the same. See the footnote under "$\overline{\nu}$ Mass Squared."

[11] BELESEV 95 (Moscow) use an integral electrostatic spectrometer with adiabatic magnetic collimation and a gaseous tritium sources. A fit to a normal Kurie plot above 18300–18350 eV (to avoid a low-energy anomaly) plus a monochromatic line 7–15 eV below the endpoint yields $m^2_\nu = -4.1 \pm 10.9$ eV^2, leading to this Bayesian limit.

[12] CHING 95 quotes results previously given by SUN 93; no experimental details are given. A possible explanation for consistently negative values of m^2_ν is given.

[13] HIDDEMANN 95 (Munich) experiment uses atomic tritium embedded in a metal-dioxide lattice. Bayesian limit calculated from the weighted mean $m^2_\nu = 221 \pm 4244$ eV^2 from the two runs listed below.

[14] STOEFFL 95 (LLNL) result is the Bayesian limit obtained from the m^2_ν errors given below but with m^2_ν set equal to 0. The anomalous endpoint accumulation leads to a value of m^2_ν which is negative by more than 5 standard deviations.

[15] WEINHEIMER 93 (Mainz) is a measurement of the endpoint of the tritium β spectrum using an electrostatic spectrometer with a magnetic guiding field. The source is molecular tritium frozen onto an aluminum substrate.

[16] HOLZSCHUH 92B (Zurich) result is obtained from the measurement $m^2_\nu = -24 \pm 48 \pm 61$ (1σ errors), in eV^2, using the PDG prescription for conversion to a limit in m_ν.

[17] KAWAKAMI 91 (Tokyo) experiment uses tritium-labeled arachidic acid. This result is the Bayesian limit obtained from the m^2_ν limit with the errors combined in quadrature. This was also done in ROBERTSON 91, although the authors report a different procedure.

[18] ROBERTSON 91 (LANL) experiment uses gaseous molecular tritium. The result is in strong disagreement with the earlier claims by the ITEP group [LUBIMOV 80, BORIS 87 (+ BORIS 88 erratum)] that m_ν lies between 17 and 40 eV. However, the probability of a positive m^2 is only 3% if statistical and systematic error are combined in quadrature.

[19] See also comment in BORIS 87B and erratum in BORIS 88.

$\overline{\nu}$ MASS SQUARED (electron based)

Given troubling systematics which result in improbably negative estimators of $m^{2(\text{eff})}_{\nu_e} \equiv \sum_i |U_{ei}|^2\ m^2_{\nu_i}$, in many experiments, we use only KRAUS 05, LOBASHEV 99, and AKER 22 for our average.

[1] AKER 22 report results from the analysis of the Tritium β spectrum using the combined data set collected by the KATRIN experiment in the first two science runs. Supersedes AKER 19.

[2] ASEEV 11 report the analysis of the entire beta endpoint data, taken with the Troitsk integrating electrostatic spectrometer between 1997 and 2002, using a windowless gaseous tritium source. The analysis does not use the two additional fit parameters (see LOBASHEV 99) for a step-like structure near the endpoint. Using only the runs where the tritium gas column density was carefully monitored the need for such parameters was eliminated. Supersedes LOBASHEV 99 and BELESEV 95.

[3] KRAUS 05 is a continuation of the work reported in WEINHEIMER 99. This result represents the final analysis of data taken from 1997 to 2001. Problems with significantly negative squared neutrino masses, observed in some earlier experiments, have been resolved in this work.

[4] AKER 19 use the first month of data collected by the KATRIN experiment to determine m_ν^2. The result is consistent with a neutrino mass of zero and is used to place a limit on m_ν. Superseded by AKER 22.

[5] LOBASHEV 99 report a new measurement which continues the work reported in BELESEV 95. The data were corrected for electron trapping effects in the source, eliminating the dependence of the fitted neutrino mass on the fit interval. The analysis assuming a pure beta spectrum yields significantly negative fitted $m_\nu^2 \approx -(20\text{–}10)$ eV^2. This problem is attributed to a discrete spectral anomaly of about 6×10^{-11} intensity with a time-dependent energy of 5–15 eV below the endpoint. The data analysis accounts for this anomaly by introducing two extra phenomenological fit parameters resulting in a best fit of $m_\nu^2 = -1.9 \pm 3.4 \pm 2.2$ eV^2 which is used to derive a neutrino mass limit. However, the introduction of phenomenological fit parameters which are correlated with the derived m_ν^2 limit makes unambiguous interpretation of this result difficult.

[6] WEINHEIMER 99 is a continuation of the work reported in WEINHEIMER 93 . Using a lower temperature of the frozen tritium source eliminated the dewetting of the T_2 film, which introduced a dependence of the fitted neutrino mass on the fit interval in the earlier work. An indication for a spectral anomaly reported in LOBASHEV 99 has been seen, but its time dependence does not agree with LOBASHEV 99. Two analyses, which exclude the spectral anomaly either by choice of the analysis interval or by using a particular data set which does not exhibit the anomaly, result in acceptable m_ν^2 fits and are used to derive the neutrino mass limit published by the authors. We list the most conservative of the two.

[7] BELESEV 95 (Moscow) use an integral electrostatic spectrometer with adiabatic magnetic collimation and a gaseous tritium sources. This value comes from a fit to a normal Kurie plot above 18300–18350 eV (to avoid a low-energy anomaly), including the effects of an apparent peak 7–15 eV below the endpoint.

[8] HIDDEMANN 95 (Munich) experiment uses atomic tritium embedded in a metal-dioxide lattice. They quote measurements from two data sets.

[9] STOEFFL 95 (LLNL) uses a gaseous source of molecular tritium. An anomalous pileup of events at the endpoint leads to the negative value for m_ν^2. The authors acknowledge that "the negative value for the best fit of m_ν^2 has no physical meaning" and discuss possible explanations for this effect.

[10] SUN 93 uses a tritiated hydrocarbon source. See also CHING 95.

[11] WEINHEIMER 93 (Mainz) is a measurement of the endpoint of the tritium β spectrum using an electrostatic spectrometer with a magnetic guiding field. The source is molecular tritium frozen onto an aluminum substrate.

[12] HOLZSCHUH 92B (Zurich) source is a monolayer of tritiated hydrocarbon.

[13] KAWAKAMI 91 (Tokyo) experiment uses tritium-labeled arachidic acid.

[14] ROBERTSON 91 (LANL) experiment uses gaseous molecular tritium. The result is in strong disagreement with the earlier claims by the ITEP group [LUBIMOV 80, BORIS 87 (+ BORIS 88 erratum)] that m_ν lies between 17 and 40 eV. However, the probability of a positive m_ν^2 is only 3% if statistical and systematic error are combined in quadrature.

ν MASS (electron based)

These are measurement of m_ν (in contrast to $m_{\overline{\nu}}$, given above). The masses can be different for a Dirac neutrino in the absence of CPT invariance. The possible distinction between ν and $\overline{\nu}$ properties is usually ignored elsewhere in these Listings.

ν MASS (muon based)

Limits given below are for the square root of $m_{\nu_\mu}^{2(\text{eff})} \equiv \sum_i |U_{\mu i}|^2 \, m_{\nu_i}^2$.

In some of the COSM papers listed below, the authors did not distinguish between weak and mass eigenstates.

OUR EVALUATION is based on OUR AVERAGE for the $\pi^\pm$ mass and the ASSAMAGAN 96 value for the muon momentum for the π^+ decay at rest. The limit is calculated using the unified classical analysis of FELDMAN 98 for a Gaussian distribution near a physical boundary. WARNING: since $m_{\nu_\mu}^{2(\text{eff})}$ is calculated from the differences of large numbers, it and the corresponding limits are extraordinarily sensitive to small changes in the pion mass, the decay muon momentum, and their errors. For example, the limits obtained using JECKELMANN 94, LENZ 98, and the weighted averages are 0.15, 0.29, and 0.19 MeV, respectively.

VALUE (MeV)	CL%	DOCUMENT ID		TECN	COMMENT

[1] ASSAMAGAN 96 measurement of p_μ from $\pi^+ \to \mu^+\nu$ at rest combined with JECKELMANN 94 Solution B pion mass yields $m_\nu^2 = -0.016 \pm 0.023$ with corresponding Bayesian limit listed above. If Solution A is used, $m_\nu^2 = -0.143 \pm 0.024$ MeV^2. Replaces ASSAMAGAN 94.

[2] DOLGOV 95 removes earlier assumptions (DOLGOV 93) about thermal equilibrium below T_{QCD} for wrong-helicity Dirac neutrinos (ENQVIST 93, FULLER 91) to set more stringent limits.

[3] ENQVIST 93 bases limit on the fact that thermalized wrong-helicity Dirac neutrinos would speed up expansion of early universe, thus reducing the primordial abundance. FULLER 91 exploits the same mechanism but in the older calculation obtains a larger production rate for these states, and hence a lower limit. Neutrino lifetime assumed to exceed nucleosynthesis time, ~ 1 s.

[4] Assumes neutrino lifetime >1 s. For Dirac neutrinos only. See also ENQVIST 93.

[5] ANDERHUB 82 kinematics is insensitive to the pion mass.

ν MASS (tau based)

The limits given below are the square roots of limits for $m_{\nu_\tau}^{2(\text{eff})} \equiv \sum_i |U_{\tau i}|^2 \, m_{\nu_i}^2$.

In some of the ASTR and COSM papers listed below, the authors did not distinguish between weak and mass eigenstates.

[1] BARATE 98F result based on kinematics of 2939 $\tau^- \to 2\pi^-\pi^+\nu_\tau$ and 52 $\tau^- \to 3\pi^-2\pi^+(\pi^0)\nu_\tau$ decays. If possible 2.5% excited a_1 decay is included in 3-prong sample analysis, limit increases to 19.2 MeV.

[2] ATHANAS 00 bound comes from analysis of $\tau^- \to \pi^-\pi^+\pi^-\pi^0\nu_\tau$ decays.

[3] ACKERSTAFF 98T use $\tau \to 5\pi^\pm\nu_\tau$ decays to obtain a limit of 43.2 MeV (95%CL). They combine this with ALEXANDER 96M value using $\tau \to 3h^\pm\nu_\tau$ decays to obtain quoted limit.

[4] AMMAR 98 limit comes from analysis of $\tau^- \to 3\pi^-2\pi^+\nu_\tau$ and $\tau^- \to 2\pi^-\pi^+2\pi^0\nu_\tau$ decay modes.

[5] ANASTASSOV 97 derive limit by comparing their m_τ measurement (which depends on m_{ν_τ}) to BAI 96 m_τ threshold measurement.

[6] FIELDS 97 limit for a Dirac neutrino. For a Majorana neutrino the mass region < 0.93 or >31 MeV is excluded. These bounds assume N_ν <4 from nucleosynthesis; a wider excluded region occurs with a smaller N_ν upper limit.

[7] SWAIN 97 derive their limit from the Standard Model relationships between the tau mass, lifetime, branching fractions for $\tau^- \to e^-\overline{\nu}_e\nu_\tau$, $\tau^- \to \mu^-\overline{\nu}_\mu\nu_\tau$, $\tau^- \to \pi^-\nu_\tau$, and $\tau^- \to K^-\nu_\tau$, and the muon mass and lifetime by assuming lepton universality and using world average values. Limit is reduced to 48 MeV when the CLEO τ mass measurement (BALEST 93) is included; see CLEO's more recent m_{ν_τ} limit (ANASTASSOV 97). Consideration of mixing with a fourth generation heavy neutrino yields $\sin^2\theta_L < 0.016$ (95%CL).

[8] ALEXANDER 96M bound comes from analyses of $\tau^- \to 3\pi^- 2\pi^+ \nu_\tau$ and $\tau^- \to h^- h^- h^+ \nu_\tau$ decays.

[9] BOTTINO 96 assumes three generations of neutrinos with mixing, finds consistency with massless neutrinos with no mixing based on 1995 data for masses, lifetimes, and leptonic partial widths.

[10] HANNESTAD 96C limit is on the mass of a Majorana neutrino. This bound assumes $N_\nu < 4$ from nucleosynthesis. A wider excluded region occurs with a smaller N_ν upper limit. This paper is the corrected version of HANNESTAD 96; see the erratum: HANNESTAD 96B.

[11] SOBIE 96 derive their limit from the Standard Model relationship between the tau mass, lifetime, and leptonic branching fraction, and the muon mass and lifetime, by assuming lepton universality and using world average values.

[12] BUSKULIC 95H bound comes from a two-dimensional fit of the visible energy and invariant mass distribution of $\tau \to 5\pi(\pi^0)\nu_\tau$ decays. Replaced by BARATE 98F.

[13] DOLGOV 95 removes earlier assumptions (DOLGOV 93) about thermal equilibrium below T_{QCD} for wrong-helicity Dirac neutrinos (ENQVIST 93, FULLER 91) to set more stringent limits. DOLGOV 96 argues that a possible window near 20 MeV is excluded.

[14] SIGL 95 exclude massive Dirac or Majorana neutrinos with lifetimes between 10^{-3} and 10^8 seconds if the decay products are predominantly γ or $e^+ e^-$.

[15] DODELSON 94 calculate constraints on ν_τ mass and lifetime from nucleosynthesis for 4 generic decay modes. Limits depend strongly on decay mode. Quoted limit is valid for all decay modes of Majorana neutrinos with lifetime greater than about 300 s. For Dirac neutrinos limits change to < 0.3 or > 33.

[16] KAWASAKI 94 excluded region is for Majorana neutrino with lifetime >1000 s. Other limits are given as a function of ν_τ lifetime for decays of the type $\nu_\tau \to \nu_\mu \phi$ where ϕ is a Nambu-Goldstone boson.

[17] PERES 94 used PDG 92 values for parameters to obtain a value consistent with mixing. Reexamination by BOTTINO 96 which included radiative corrections and 1995 PDG parameters resulted in two allowed regions, $m_3 < 70$ MeV and 140 MeV $m_3 < 149$ MeV.

[18] CINABRO 93 bound comes from analysis of $\tau^- \to 3\pi^- 2\pi^+ \nu_\tau$ and $\tau^- \to 2\pi^- \pi^+ 2\pi^0 \nu_\tau$ decay modes.

[19] DOLGOV 93 assumes neutrino lifetime >100 s. For Majorana neutrinos, the low mass limit is 0.5 MeV. KAWANO 92 points out that these bounds can be overcome for a Dirac neutrino if it possesses a magnetic moment. See also DOLGOV 96.

[20] ENQVIST 93 bases limit on the fact that thermalized wrong-helicity Dirac neutrinos would speed up expansion of early universe, thus reducing the primordial abundance. FULLER 91 exploits the same mechanism but in the older calculation obtains a larger production rate for these states, and hence a lower limit. Neutrino lifetime assumed to exceed nucleosynthesis time, ~ 1 s.

[21] ALBRECHT 92M reports measurement of a slightly lower τ mass, which has the effect of reducing the ν_τ mass reported in ALBRECHT 88B. Bound is from analysis of $\tau^- \to 3\pi^- 2\pi^+ \nu_\tau$ mode.

[22] Assumes neutrino lifetime >1 s. For Dirac neutrinos. See also ENQVIST 93.

[23] KOLB 91 exclusion region is for Dirac neutrino with lifetime >1 s; other limits are given.

Revised August 2023 by K.A. Olive (University of Minnesota).

Neutrinos decouple from thermal equilibrium in the early universe at temperatures $\mathcal{O}(1)$ MeV. The limits on low mass ($m_\nu \lesssim 1$ MeV) neutrinos apply to $m_{\rm tot}$ given by

$$m_{\rm tot} = \sum_\nu m_\nu \ .$$

Stable neutrinos in this mass range decouple from the thermal bath while still relativistic and make a contribution to the total energy density of the Universe which is given by

$$\rho_\nu = m_{\rm tot} n_\nu \simeq m_{\rm tot}(3/11)(3.045/3)^{3/4} n_\gamma \ ,$$

where the factor 3/11 is the ratio of (light) neutrinos to photons and the factor $(3.045/3)^{3/4}$ corrects for the fact that the effective number of neutrinos in the standard model is 3.045 when taking into account e^+e^- annihilation during neutrino decoupling. Writing $\Omega_\nu = \rho_\nu/\rho_c$, where ρ_c is the critical energy density of the Universe, and using $n_\gamma = 410.7\ {\rm cm}^{-3}$, we have

$$\Omega_\nu h^2 \simeq m_{\rm tot}/(93\ {\rm eV}) \ .$$

While an upper limit to the matter density of $\Omega_m h^2 < 0.12$ would constrain $m_{\rm tot} < 11$ eV, much stronger constraints are obtained from the observations of the CMB, combined with lensing and baryon acoustic oscillations data. These combine to give an upper limit of around 0.12 eV, and may, in the near future, be able to provide a lower bound on the sum of the neutrino masses. The current lower bound of $m_{\rm tot} > 0.06$ eV implies a lower limit of $\Omega_\nu h^2 > 6 \times 10^{-4}$. See our review on "Neutrinos in Cosmology" for more details.

SUM OF THE NEUTRINO MASSES, $m_{\rm tot}$

This is a sum of the neutrino masses, $m_{\rm tot}$, as defined in the above note, of effectively stable neutrinos, i.e. those with mean lifetimes on cosmological scales. When necessary, we have generalized the results reported so they apply to $m_{\rm tot}$. For other limits, see SZALAY 76, VYSOTSKY 77, BERNSTEIN 81, FREESE 84, SCHRAMM 84, and COWSIK 85. For more information see a note on "Neutrinos in Cosmology" in this *Review*.

[1] BRIEDEN 22 combines redshift-space distortions and the shape of the matter power spectrum from BOSS and eBOSS data together with Planck CMB data. Absent the CMB data, the limit is 0.40 eV.

[2] KUMAR 22 combine the reconstructed galaxy power spectrum from BOSS data with Planck CMB data.

[3] TANSERI 22 combines BOSS galaxy clustering data with measurements of CMB data. Updates VAGNOZZI 17.

[4] ABBOTT 21A combines Dark Energy Survey (DES) year 3 results with Planck CMB lensing measurements.

[5] ALAM 21 limit on the sum of neutrino masses by the eBOSS collaboration is based on galaxy, quasar, and Lyman-α 3D clustering data combined with Planck temperature and polarization CMB and supernovae data.

[6] DI-VALENTINO 21 combines CMB temperature and polarization, SNIa luminosity distances and baryon acoustic oscillations data.

[7] GARNY 21 employs a model for the Lyman-α flux power spectrum to set a limit using BOSS data. When combined with Planck CMB temperature and polarization data, a 95% CL range 0.10–0.13 eV is found.

[8] STOCKER 21 use terrestrial and cosmological experiments to set a 95% CL range on the sum of neutrino masses of 0.058–0.139 eV for normal ordering and 0.098–0.174 eV for inverse ordering. They also set an upper limit of 0.037 eV (NO) and 0.042 eV (IO) for the lightest neutrino mass.

[9] AGHANIM 20 limit on the sum of neutrino masses from Planck data combined with lensing and baryon acoustic oscillations (BAO). Without BAO, the limit relaxes to <0.24 eV. Several other limits are quoted based on different combinations of data.

[10] CHOUDHURY 20 combines 2018 Planck CMB temperature and polarization data plus lensing, together with baryon acoustic oscillation data from BOSS, MGS, and 6dFGS. Assumes ΛCDM model. The upper limit is 0.17 eV for the inverted hierarchy, and 0.12 eV for degenerate neutrinos. Limits are also derived for extended cosmological models.

[11] IVANOV 20 combines 2018 Planck CMB data with baryon acoustic oscillation data from BOSS. This study is based on a full-shape likelihood for the redshift-space galaxy power spectrum of the BOSS data.

[12] PALANQUE-DELABROUILLE 20 combine Lyman alpha and Planck temperature and polarization data. Limit improves to 0.09 eV when CMB lensing and baryon acoustic oscillation data are included.

[13] LOUREIRO 19 combines data from large scale structure, cosmic microwave background, type Ia supernovae and big bang nucleosynthesis using physically motivated neutrino mass models.

[14] UPADHYE 19 uses the shape of the BOSS redshift-space galaxy power spectrum in combination with the CMB, and supernovae data. Limit weakens to $<$ 0.54 eV if the dark energy equation of state is allowed to vary.

[15] CHOUDHURY 18 combines 2015 Planck CMB temperature data, information from the optical depth to reionization from Planck 2016 intermediate results together with baryon acoustic oscillation data from BOSS, MGS, and 6dFGS as well as supernovae Type Ia data from the Pantheon Sample. The limit is strengthened to 0.118 eV when high-l CMB polarization data is also included.

[16] SIMPSON 17 uses a combination of laboratory and cosmological measurements to determine the light neutrino masses and argue that there is strong evidence for the normal mass ordering.

[17] Constrains the total mass of neutrinos using the Lyman-alpha forest power spectrum with BOSS (mid-resolution), XQ-100 (high-resolution) and CMB. Without the CMB data, the limit relaxes to 0.8 eV. Supersedes PALANQUE-DELABROUILLE 15A.

[18] Constrains the total mass of neutrinos from Planck CMB data combined with baryon acoustic oscillation and Planck cluster data.

[19] Constrains the total mass of neutrinos from BAO data from SDSS-III/BOSS combined with CMB data from Planck. Limit quoted for normal mass hierarchy. The limit for the inverted mass hierarchy is 0.20 eV and for the degenerate mass hierarchy it is 0.15 eV.

[20] ROSSI 15 sets limits on the sum of neutrino masses using BOSS Lyman alpha forest data combined with Planck CMB data and baryon acoustic oscillations.

[21] Constrains the total mass of neutrinos from Planck CMB data along with WMAP polarization, high L, and BAO data.

[22] Finite neutrino mass fit to resolve discrepancy between CMB and lensing measurements.

[23] Fit to the total mass of neutrinos from BOSS data along with WMAP CMB data and data from other BAO constraints and weak lensing.

[24] Fit to the total mass of neutrinos from Planck CMB data along with BAO.

[25] Fit based on the SPT-SZ survey combined with CMB, BAO, and H_0 data.

[26] Constraints the total mass of neutrinos (marginalizing over the effective number of neutrino species) from CMB, CMB lensing, BAO, and galaxy clustering data.

[27] Constrains the total mass of neutrinos from Planck CMB data combined with baryon acoustic oscillation data from BOSS, 6dFGS, SDSS, WiggleZ data on the galaxy power spectrum, and HST data on the Hubble parameter. The limit is increased to 0.25 eV if a lower bound to the sum of neutrino masses of 0.04 eV is assumed.

[28] Constrains the total mass of neutrinos from observational Hubble parameter data with seven-year WMAP data and the most recent estimate of H_0.

[29] Constrains the total mass of neutrinos from the CFHTLS combined with seven-year WMAP data and a prior on the Hubble parameter. Limit is relaxed to 0.41 eV when small scales affected by non-linearities are removed.

[30] Constrains the total mass of neutrinos from the Sloan Digital Sky Survey and the five-year WMAP data.

[31] Constrains the total mass of neutrinos from the 7-year WMAP data including SDSS and HST data. Limit relaxes to 1.19 eV when CMB data is used alone. Supersedes HANNESTAD 06.

[32] Constrains the total mass of neutrinos from a combination of CMB data, a recent measurement of H_0 (SHOES), and baryon acoustic oscillation data from SDSS.

[33] Constrains the total mass of neutrinos from SDSS MegaZ LRG DR7 galaxy clustering data combined with CMB, HST, supernovae and baryon acoustic oscillation data. Limit relaxes to 0.47 eV when the equation of state parameter, $w \neq 1$.

[34] Constrains the total mass of neutrinos from weak lensing measurements when combined with CMB. Limit improves to 0.54 eV when supernovae and baryon acoustic oscillation observations are included. Assumes ΛCDM model.

[35] Constrains the total mass of neutrinos from five-year WMAP data. Limit improves to 0.67 eV when supernovae and baryon acoustic oscillation observations are included. Limits quoted assume the ΛCDM model. Supersedes SPERGEL 07.

[36] Constrains the total mass of neutrinos from weak lensing measurements when combined with CMB. Limit improves to $0.03 < \Sigma m_\nu < 0.54$ eV when supernovae and baryon acoustic oscillation observations are included. The slight preference for massive neutrinos at the two-sigma level disappears when systematic errors are taken into account. Assumes ΛCDM model.

[37] Constrains the total mass of neutrinos from recent Chandra X-ray observations of galaxy clusters when combined with CMB, supernovae, and baryon acoustic oscillation measurements. Assumes flat universe and constant dark-energy equation of state, w.

[38] Constraints the total mass of neutrinos from recent CMB and SOSS LRG power spectrum data along with bias mass relations from SDSS, DEEP2, and Lyman-Break Galaxies. It assumes ΛCDM model. Limit degrades to 0.59 eV in a more general wCDM model.

[39] Constrains the total mass of neutrinos from neutrino oscillation experiments and cosmological data. The most conservative limit uses only WMAP three-year data, while the most stringent limit includes CMB, large-scale structure, supernova, and Lyman-alpha data.

[40] Constrains the total mass of neutrinos from recent CMB, large scale structure, SN1a, and baryon acoustic oscillation data. The limit relaxes to 1.75 when WMAP data alone is used with no prior. Paper shows results with several combinations of data sets. Supersedes KRISTIANSEN 06.

[41] Constrains the total mass of neutrinos from the CMB and the large scale structure data. The most conservative limit is obtained when generic initial conditions are allowed.

[42] Constrains the total mass of neutrinos from recent CMB, large scale structure, Lyman-alpha forest, and SN1a data.

[43] Constrains the total mass of neutrinos from recent CMB and large scale structure data. See also GOOBAR 06. Superseded by HANNESTAD 10.

[44] Constrains the total mass of neutrinos from the CMB and the final 2dF Galaxy Redshift Survey.

[45] Constrains the total mass of neutrinos from the CMB experiments alone, assuming ΛCDM Universe. FUKUGITA 06 show that this result is unchanged by the 3-year WMAP data.

[46] Constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the Sloan Digital Sky Survey and the 2dF galaxy redshift survey, WMAP and 27 other CMB experiments and measurements by the HST Key project.

[47] Constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the Sloan Digital Sky Survey, the 2dF galaxy redshift survey, WMAP and ACBAR. The limit is strengthened to 0.6 eV when measurements by the HST Key project and supernovae data are included.

[48] Constrains the fractional contribution of neutrinos to the total matter density in the Universe from WMAP data combined with other CMB measurements, the 2dfGRS data, and Lyman α data. The limit does not noticeably change if the Lyman α data are not used.

[49] LEWIS 02 constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the CMB, HST Key project, 2dF galaxy redshift survey, supernovae type Ia, and BBN.

[50] WANG 02 constrains the total mass of neutrinos from the power spectrum of fluctuations derived from the CMB and other cosmological data sets such as galaxy clustering and the Lyman α forest.

[51] FUKUGITA 00 is a limit on neutrino masses from structure formation. The constraint is based on the clustering scale σ_8 and the COBE normalization and leads to a conservative limit of 0.9 eV assuming 3 nearly degenerate neutrinos. The quoted limit is on the sum of the light neutrino masses.

[52] CROFT 99 result based on the power spectrum of the Ly α forest. If $\Omega_{\rm matter} < 0.5$, the limit is improved to $m_\nu < 2.4\ (\Omega_{\rm matter}/0.17\text{–}1)$ eV.

Limits on MASSES of Light Stable Right-Handed ν (with necessarily suppressed interaction strengths)

VALUE (eV)	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
<100–200	[1] OLIVE	82	COSM	Dirac ν
<200–2000	[1] OLIVE	82	COSM	Majorana ν

[1] Depending on interaction strength G_R where $G_R < G_F$.

Limits on MASSES of Heavy Stable Right-Handed ν (with necessarily suppressed interaction strengths)

VALUE (GeV)	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
> 10	[1] OLIVE	82	COSM	G_R/G_F <0.1
>100	[1] OLIVE	82	COSM	G_R/G_F <0.01

[1] These results apply to heavy Majorana neutrinos and are summarized by the equation: m_ν >1.2 GeV (G_F/G_R). The bound saturates, and if G_R is too small no mass range is allowed.

ν CHARGE

$<1 \times 10^{-13}$		[16] BERNSTEIN	63	ASTR	solar energy losses

[1] CAPRINI 05 limit derived from the lack of a charge asymmetry in the universe. Limit assumes that charge asymmetries between particles are not anti-correlated.

[2] AALBERS 23A utilize the first 60 days of data collected by the LZ dark matter search to place a limit on the electric charge of solar neutrinos. Low energy electron-recoil events are utilized. This LZ-collaboration analysis supersedes that of the external authors in ATZORI-CORONA 23 because of a more complete treatment of experiment uncertainties.

[3] ATZORI-CORONA 23 use LUX-ZEPLIN dark matter search data published by AALBERS 23 to place a limit on neutrino millicharge.

[4] BONET 22A use data collected by four low-threshold Ge detectors, placed 17.1 m from one of the cores of the nuclear reactors at Brokdorf to derive this limit. A spectral analysis is performed on reactor on and off data.

[5] ABE 20E obtains this result by assuming that the low-energy excess events in the XMASS detector are produced by neutrino millicharge which is common for all three neutrino flavors.

[6] KHAN 20 performed a constrained spectral fit analysis of the excess observed in the electron recoil energy spectrum by the XENON1T experiment. This range of neutrino millicharge values is one of the possible interpretations of these excess events. For the individual flavor constraints at 90% C.L. see the original reference.

[7] DELLA-VALLE 16 obtain a limit on the charge of neutrinos valid for masses of less than 10 meV. For heavier neutrinos the limit increases as a power of mass, reaching 10^{-6} e for $m = 100$ meV.

[8] CHEN 14A use the Multi-Configuration RRPA method to analyze reactor $\overline{\nu}_e$ scattering on Ge atoms with 300 eV recoil energy threshold to obtain this limit.

[9] STUDENIKIN 14 uses the limit on μ_ν from BEDA 13 and the 2.8 keV threshold of the electron recoil energy to obtain this limit.

[10] GNINENKO 07 use limit on $\overline{\nu}_e$ magnetic moment from LI 03B to derive this result. The limit is considerably weaker than the limits on the charge of ν_e and $\overline{\nu}_e$ from various astrophysics considerations.

[11] This RAFFELT 99 limit applies to all neutrino flavors which are light enough (<5 keV) to be emitted from globular-cluster red giants.

[12] This RAFFELT 99 limit is derived from the helioseismological limit on a new energy-loss channel of the Sun, and applies to all neutrino flavors which are light enough (<1 keV) to be emitted from the sun.

[13] BABU 94 use COOPER-SARKAR 92 limit on ν magnetic moment to derive quoted result. It applies to ν_τ.

[14] DAVIDSON 91 use data from early SLAC electron beam dump experiment to derive charge limit as a function of neutrino mass. It applies to ν_τ.

[15] Exact BARBIELLINI 87 limit depends on assumptions about the intergalactic or galactic magnetic fields and about the direct distance and time through the field. It applies to ν_e.

[16] The limit applies to all flavors.

ν (MEAN LIFE) / MASS

Measures $\left[\sum |U_{\ell j}|^2 \, \Gamma_j \, m_j\right]^{-1}$, where the sum is over mass eigenstates which cannot be resolved experimentally. Some of the limits constrain the radiative decay and are based on the limit of the corresponding photon flux. Other apply to the decay of a heavier neutrino into the lighter one and a Majoron or other invisible particle. Many of these limits apply to any ν within the indicated mass range.

Limits on the radiative decay are either directly based on the limits of the corresponding photon flux, or are derived from the limits on the neutrino magnetic moments. In the later case the transition rate for $\nu_i \to \nu_j + \gamma$ is constrained by $\Gamma_{ij} = \frac{1}{\tau_{ij}} = \frac{(m_i^2 - m_j^2)^3}{m_i^3} \mu_{ij}^2$ where μ_{ij} is the neutrino transition moment in the mass eigenstates basis. Typically, the limits on lifetime based on the magnetic moments are many orders of magnitude more restrictive than limits based on the nonobservation of photons.

[1] KRAKAUER 91 quotes the limit $\tau/m_{\nu_1} > (0.75a^2 + 21.65a + 26.3)$ s/eV, where a is a parameter describing the asymmetry in the neutrino decay defined as $dN_\gamma/d\cos\theta = (1/2)(1 + a\cos\theta)$ The parameter $a = 0$ for a Majorana neutrino, but can vary from -1 to 1 for a Dirac neutrino. The bound given by the authors is the most conservative (which applies for $a = -1$).

[2] RAFFELT 85 limit on the radiative decay is from solar x- and γ-ray fluxes. Limit depends on ν flux from pp, now established from GALLEX and SAGE to be > 0.5 of expectation.

[3] REINES 74 looked for ν of nonzero mass decaying radiatively to a neutral of lesser mass + γ. Used liquid scintillator detector near fission reactor. Finds lab lifetime 6×10^7 s or more. Above value of (mean life)/mass assumes average effective neutrino energy of 0.2 MeV. To obtain the limit 6×10^7 s REINES 74 assumed that the full $\overline{\nu}_e$ reactor flux could be responsible for yielding decays with photon energies in the interval 0.1 MeV – 0.5 MeV. This represents some overestimate so their lower limit is an over-estimate of the lab lifetime (VOGEL 84). If so, OBERAUER 87 may be comparable or better.

[4] IVANEZ-BALLESTEROS 23 reports a limit on the lifetime-to-mass ratio of the mass eigenstates ν_1 and ν_2 for inverted mass ordering. No limit was obtained in the case of normal mass ordering.

[5] AHARMIM 19 quotes the limit τ/m_{ν_2} for invisible nonradiative decay of ν_2. They obtained this result by analyzing the entire SNO dataset, allowing for the decay of ν_2 which would cause an energy-dependent distortion of the survival probability of electron-type solar neutrinos.

[6] AHARMIM 19 quotes the limit τ/m_{ν_2} for invisible nonradiative decay of ν_2. They obtained this result by combining the τ/m_{ν_2} measurements from SNO and other solar neutrino experiments (Super-Kamiokande, KamLAND, and Borexino ^{8}B results; Borexino and KamLAND ^{7}Be results; the combined gallium interaction rate from GNO, GALLEX, and SAGE; and the chlorine interaction rate from Homestake). The quoted limit at 99% CL is $> 1.04 \times 10^{-3}$.

[7] ESCUDERO 19 sets limits on invisible neutrino decays using Planck 2018 data of $\tau > 1.3–0.3 \times 10^9$ s at 95% C.L. Values in the range $\tau = 2–16 \times 10^9$ s are preferred at 95% C.L. when Planck polarization data is included. Limits scale as $(m_\nu/0.05 \text{ eV})^3$.

[8] CECCHINI 11 search for radiative decays of solar neutrinos into visible photons during the 2006 total solar eclipse. The range of (mean life)/mass values corresponds to a range of ν_1 masses between 10^{-4} and 0.1 eV.

[9] MIRIZZI 07 determine a limit on the neutrino radiative decay from analysis of the maximum allowed distortion of the CMB spectrum as measured by the COBE/FIRAS. For the decay $\nu_2 \to \nu_1$ the lifetime limit is $\lesssim 4 \times 10^{20}$ s for $m_{min} \lesssim 0.14$ eV. For transition with the $|\Delta m_{31}|$ mass difference the lifetime limit is $\sim 2 \times 10^{19}$ s for $m_{min} \lesssim 0.14$ eV and $\sim 5 \times 10^{20}$ s for $m_{min} \gtrsim 0.14$ eV.

[10] MIRIZZI 07 determine a limit on the neutrino radiative decay from analysis of the cosmic infrared background (CIB) using the Spitzer Observatory data. For transition with the $|\Delta m_{31}|$ mass difference they obtain the lifetime limit $\sim 10^{20}$ s for $m_{min} \lesssim 0.14$ eV.

[11] WONG 07 use their limit on the neutrino magnetic moment together with the assumed experimental value of $\Delta m^2_{13} \sim 2\times10^{-3}$ eV^2 to obtain $\tau_{13}/m_1^3 > 3.2\times10^{27}$ s/eV^3 for the radiative decay in the case of the inverted mass hierarchy. Similarly to RAFFELT 89 this limit can be violated if electric and magnetic moments are equal to each other. Analogous, but numerically somewhat different limits are obtained for τ_{23} and τ_{21}.

[12] XIN 05 search for the γ from radiative decay of ν_e produced by the electron capture on ^{51}Cr. No events were seen and the limit on τ/m_ν was derived. This is a weaker limit on the decay of ν_e than KRAKAUER 91.

[13] XIN 05 use their limit on the neutrino magnetic moment of ν_e together with the assumed experimental value of $\Delta m^2_{1,3} \sim 2\times10^{-3}$ eV^2 to obtain $\tau_{13}/m_1^3 > 1\times10^{23}$ s/eV^3 for the radiative decay in the case of the inverted mass hierarchy. Similarly to RAFFELT 89 this limit can be violated if electric and magnetic moments are equal to each other. Analogous, but numerically somewhat different limits are obtained for τ_{23} and τ_{21}. Again, this limit is specific for ν_e.

[14] AHARMIM 04 obtained these results from the solar $\overline{\nu}_e$ flux limit set by the SNO measurement assuming ν_2 decay through nonradiative process $\nu_2 \to \overline{\nu}_1 X$, where X is a Majoron or other invisible particle. Limits are given for the cases of quasidegenerate and hierarchical neutrino masses.

[15] CECCHINI 04 obtained this bound through the observations performed on the occasion of the 21 June 2001 total solar eclipse, looking for visible photons from radiative decays of solar neutrinos. Limit is a τ/m_{ν_2} in $\nu_2 \to \nu_1\gamma$. Limit ranges from $\sim$ 100 to 10^7 s/eV for $0.01 < m_{\nu_1} < 0.1$ eV.

[16] EGUCHI 04 obtained these results from the solar $\overline{\nu}_e$ flux limit set by the KamLAND measurement assuming ν_2 decay through nonradiative process $\nu_2 \to \overline{\nu}_1 X$, where X is a Majoron or other invisible particle. Limits are given for the cases of quasidegenerate and hierarchical neutrino masses.

[17] The ratio of the lifetime over the mass derived by BANDYOPADHYAY 03 is for ν_2. They obtained this result using the following solar-neutrino data: total rates measured in Cl and Ga experiments, the Super-Kamiokande's zenith-angle spectra, and SNO's day and night spectra. They assumed that ν_1 is the lowest mass, stable or nearly stable neutrino state and ν_2 decays through nonradiative Majoron emission process, $\nu_2 \to \overline{\nu}_1 + J$, or through nonradiative process with all the final state particles being sterile. The best fit is obtained in the region of the LMA solution.

[18] DERBIN 02B (also BACK 03B) obtained this bound for the radiative decay from the results of background measurements with Counting Test Facility (the prototype of the Borexino detector). The laboratory gamma spectrum is given as $dN_\gamma/d\cos\theta = (1/2)\,(1 + \alpha\cos\theta)$ with α=0 for a Majorana neutrino, and α varying to -1 to 1 for a Dirac neutrino. The listed bound is for the case of α=0. The most conservative bound 1.5×10^3 s eV^{-1} is obtained for the case of α=-1.

[19] The ratio of the lifetime over the mass derived by JOSHIPURA 02B is for ν_2. They obtained this result from the total rates measured in all solar neutrino experiments. They assumed that ν_1 is the lowest mass, stable or nearly stable neutrino state and ν_2 decays through nonradiative process like Majoron emission decay, $\nu_2 \to \nu_1' + J$ where ν_1' state is sterile. The exact limit depends on the specific solution of the solar neutrino problem. The quoted limit is for the LMA solution.

[20] DOLGOV 99 places limits in the (Majorana) τ-associated ν mass-lifetime plane based on nucleosynthesis. Results would be considerably modified if neutrino oscillations exist.

[21] BILLER 98 use the observed TeV γ-ray spectra to set limits on the mean life of any radiatively decaying neutrino between 0.05 and 1 eV. Curve shows $\tau_\nu/B_\gamma > 0.15\times10^{21}$ s at 0.05 eV, $> 1.2\times10^{21}$ s at 0.17 eV, $> 3\times10^{21}$ s at 1 eV, where B_γ is the branching ratio to photons.

[22] BLUDMAN 92 sets additional limits by this method for higher mass ranges. Cosmological limits are also obtained.

[23] Limit on the radiative decay based on nonobservation of γ's in coincidence with ν's from SN 1987A.

[24] DODELSON 92 range is for wrong-helicity keV mass Dirac ν's from the core of neutron star in SN 1987A decaying to ν's that would have interacted in KAM2 or IMB detectors.

[25] GRANEK 91 considers heavy neutrino decays to $\gamma\nu_L$ and $3\nu_L$, where m_{ν_L} <100 keV. Lifetime is calculated as a function of heavy neutrino mass, branching ratio into $\gamma\nu_L$, and m_{ν_L}.

[26] KRAKAUER 91 quotes the limit for ν_e, $\tau/m_\nu > (0.3a^2 + 9.8a + 15.9)$ s/eV, where a is a parameter describing the asymmetry in the radiative neutrino decay defined as $dN_\gamma/d\cos\theta = (1/2)(1 + a\cos\theta)$ a=0 for a Majorana neutrino, but can vary from -1 to 1 for a Dirac neutrino. The bound given by the authors is the most conservative (which applies for $a = -1$).

[27] WALKER 90 uses SN 1987A γ flux limits after 289 days.

[28] CHUPP 89 should be multiplied by a branching ratio (about 1) and a detection efficiency (about 1/4), and pertains to radiative decay of any neutrino to a lighter or sterile neutrino.

[29] RAFFELT 89 uses KYULDJIEV 84 to obtain $\tau m^3 > 3\times10^{18}$ s eV^3 (based on $\overline{\nu}_e e^-$ cross sections). The bound for the radiative decay is not valid if electric and magnetic transition moments are equal for Dirac neutrinos.

[30] RAFFELT 89B analyze stellar evolution and exclude the region $3\times10^{12} < \tau m^3 < 3\times10^{21}$ s eV^3.

[31] Model-dependent theoretical analysis of SN 1987A neutrinos. Quoted limit is for $\left[\sum_j |U_{\ell j}|^2\,\Gamma_j\, m_j\right]^{-1}$, where ℓ=μ, τ. Limit is 3.3×10^{14} s/eV for ℓ=e.

[32] OBERAUER 87 looks for photons and e^+e^- pairs from radiative decays of reactor neutrinos.

[33] BINETRUY 84 finds $\tau < 10^8$ s for neutrinos in a radiation-dominated universe.

[34] These experiments look for $\nu_k \to \nu_j\gamma$ or $\overline{\nu}_k \to \overline{\nu}_j\gamma$.

[35] STECKER 80 limit based on UV background; result given is $\tau > 4\times10^{22}$ s at m_ν=20 eV.

[36] FALK 78 finds lifetime constraints based on supernova energetics.

[37] COWSIK 77 considers variety of scenarios. For neutrinos produced in the big bang, present limits on optical photon flux require $\tau > 10^{23}$ s for $m_\nu \sim 1$ eV. See also COWSIK 79 and GOLDMAN 79.

ν MAGNETIC MOMENT

The coupling of neutrinos to an electromagnetic field is a characterized by a 3×3 matrix λ of the magnetic (μ) and electric (d) dipole moments ($\lambda = \mu - id$). For Majorana neutrinos the matrix λ is antisymmetric and only transition moments are allowed, while for Dirac neutrinos λ is a general 3×3 matrix. In the standard electroweak theory extended to include neutrino masses (see FUJIKAWA 80) $\mu_\nu = 3eG_F m_\nu/(8\pi^2\sqrt{2}) = 3.2\times10^{-19}(m_\nu/\text{eV})\mu_B$, i.e. it is unobservably small given the known small neutrino masses. In more general models there is no longer a proportionality between neutrino mass and its magnetic moment, even though only massive neutrinos have nonvanishing magnetic moments without fine tuning.

Laboratory bounds on λ are obtained via elastic ν-e scattering, where the scattered neutrino is not observed. The combinations of matrix elements of λ that are constrained by various experiments depend on the initial neutrino flavor and on its propagation between source and detector (e.g., solar ν_e and reactor $\overline{\nu}_e$ do not constrain the same combinations). The listings below therefore identify the initial neutrino flavor.

Other limits, e.g. from various stellar cooling processes, apply to all neutrino flavors. Analogous flavor independent, but weaker, limits are obtained from the analysis of $e^+e^- \to \nu\overline{\nu}\gamma$ collider experiments.

[1] APRILE 22B use data collected with the XENONnT dark matter detector to place a limit on an enhanced magnetic moment of solar neutrinos. Supersedes APRILE 20.

[2] BEDA 13 report $\overline{\nu}_e e^-$ scattering results, using the Kalinin Nuclear Power Plant and a shielded Ge detector. The recoil electron spectrum is analyzed between 2.5 and 55 keV. Supersedes BEDA 07. Supersedes BEDA 10. This is the most stringent limit on the magnetic moment of reactor $\overline{\nu}_e$.

[3] AUERBACH 01 limit is based on the LSND ν_e and ν_μ electron scattering measurements. The limit is slightly more stringent than KRAKAUER 90.

[4] SCHWIENHORST 01 quote an experimental sensitivity of 4.9×10^{-7}.

[5] AALBERS 23A utilize the first 60 days of data collected by the LZ dark matter search to place a limit on the magnetic moment of solar neutrinos. Low energy electron-recoil events are utilized. This LZ-collaboration analysis supersedes that of the external authors in ATZORI-CORONA 23 because of a more complete treatment of experiment uncertainties.

[6] ATZORI-CORONA 23 use LUX-ZEPLIN dark matter search data published by AALBERS 23 to place a limit on an enhanced magnetic moment of solar neutrinos.

[7] BONET 22A use data collected by four low-threshold Ge detectors, placed 17.1 m from one of the cores of the nuclear reactors at Brokdorf to derive this limit. A spectral analysis is performed on reactor on and off data.

[8] COLOMA 22 present a re-analysis of data taken by the COHERENT and Dresden-II experiments. The combination of both experiments is used to place a limit on the magnetic moment of electron-type neutrinos. The presented value is one-sided limit as recommended by the authors; the two-sided limit is $< 3.2 \times 10^{-10} \mu_B$ at 90% C.L. Results based on Fef and YBe quenching models are reported in the paper. The authors are not part of either collaboration.

[9] ABE 20E observed an excess of low-energy events in the XMASS detector, which could be interpreted as a signal produced by a neutrino magnetic moment with this magnitude.

[10] APRILE 20 observed an excess of low-energy events in the XENON1T detector, which could be interpreted as a signal produced by a neutrino magnetic moment with this magnitude.

[11] CAPOZZI 20 obtains a limit on the neutrino dipole moment from the brightness of the tip of the red-giant branch in ω Centauri. A similar limit of $\mu_\nu < 1.5 \times 10^{-12}\ \mu_B$ is obtained in NGC 4258.

[12] KHAN 20 performed a constrained spectral fit analysis of the excess observed in the electron recoil energy spectrum by the XENON1T experiment. This range of the μ_B values is one of the possible interpretations of these excess events. For the individual flavor constraints at 90% C.L. see the original reference.

[13] AGOSTINI 17A obtained this limit using the shape of the recoil electron energy spectrum from the Borexino Phase-II 1291.5 live days of solar neutrino data and the constraints on the sum of the solar neutrino fluxes from the radiochemical gallium experiments SAGE, Gallex, and GNO. Without radiochemical constraints, the 90% C.L. limit of $< 4.0 \times 10^{-11} \mu_B$ is obtained.

[14] ARCEO-DIAZ 15 constrains the neutrino magnetic moment from observation of the tip of the red giant branch in the globular cluster ω-Centauri.

[15] CORSICO 14 constrains the neutrino magnetic moment from observations of white drarf pulsations.

[16] MILLER-BERTOLAMI 14B constrains the neutrino magnetic moment from observations of the white dwarf luminosity function of the Galactic disk.

[17] VIAUX 13A constrains the neutrino magnetic moment from observations of the globular cluster M5.

[18] BEDA 10 report $\overline{\nu}_e e^-$ scattering results, using the Kalinin Nuclear Power Plant and a shielded Ge detector. The recoil electron spectrum is analyzed between 2.9 and 45 keV. Supersedes BEDA 07. Superseded by BEDA 13.

[19] DENIZ 10 observe reactor $\overline{\nu}_e e$ scattering with recoil kinetic energies 3–8 MeV using CsI(Tl) detectors. The observed rate and spectral shape are consistent with the Standard Model prediction, leading to the reported constraint on $\overline{\nu}_e$ magnetic moment.

[20] KUZNETSOV 09 obtain a limit on the flavor averaged magnetic moment of Dirac neutrinos from the time averaged neutrino signal of SN1987A. Improves and supersedes the analysis of BARBIERI 88 and AYALA 99.

[21] ARPESELLA 08A obtained this limit using the shape of the recoil electron energy spectrum from the Borexino 192 live days of solar neutrino data.

[22] BEDA 07 performed search for electromagnetic $\overline{\nu}_e$-e scattering at Kalininskaya nuclear reactor. A Ge detector with active and passive shield was used and the electron recoil spectrum between 3.0 and 61.3 keV analyzed. Superseded by BEDA 10.

[23] WONG 07 performed search for non-standard $\overline{\nu}_e$-e scattering at the Kuo-Sheng nuclear reactor. Ge detector equipped with active anti-Compton shield is used. Most stringent laboratory limit on magnetic moment of reactor $\overline{\nu}_e$. Supersedes LI 03B.

[24] DARAKTCHIEVA 05 present the final analysis of the search for non-standard $\overline{\nu}_e$-e scattering component at Bugey nuclear reactor. Full kinematical event reconstruction of both the kinetic energy above 700 keV and scattering angle of the recoil electron, by use of TPC. Most stringent laboratory limit on magnetic moment. Supersedes DARAKTCHIEVA 03.

[25] XIN 05 evaluated the ν_e flux at the Kuo-Sheng nuclear reactor and searched for non-standard ν_e-e scattering. Ge detector equipped with active anti-Compton shield was used. This laboratory limit on magnetic moment is considerably less stringent than the limits for reactor $\overline{\nu}_e$, but is specific to ν_e.

[26] GRIFOLS 04 obtained this bound using the SNO data of the solar ^{8}B neutrino flux measured with deuteron breakup. This bound applies to $\mu_{\rm eff} = (\mu_{21}^2 + \mu_{22}^2 + \mu_{23}^2)^{1/2}$.

[27] LIU 04 obtained this limit using the shape of the recoil electron energy spectrum from the Super-Kamiokande-I 1496 days of solar neutrino data. Neutrinos are assumed to have only diagonal magnetic moments, $\mu_{\nu 1} = \mu_{\nu 2}$. This limit corresponds to the oscillation parameters in the vacuum oscillation region.

[28] LIU 04 obtained this limit using the shape of the recoil electron energy spectrum from the Super-Kamiokande-I 1496 live-day solar neutrino data, by limiting the oscillation parameter region in the LMA region allowed by solar neutrino experiments plus KamLAND. $\mu_{\nu 1} = \mu_{\nu 2}$ is assumed. In the LMA region, the same limit would be obtained even if neutrinos have off-diagonal magnetic moments.

[29] BACK 03B obtained this bound from the results of background measurements with Counting Test Facility (the prototype of the Borexino detector). Standard Solar Model flux was assumed. This μ_ν can be different from the reactor μ_ν in certain oscillation scenarios (see BEACOM 99).

[30] DARAKTCHIEVA 03 searched for non-standard $\overline{\nu}_e$-e scattering component at Bugey nuclear reactor. Full kinematical event reconstruction by use of TPC. Superseded by DARAKTCHIEVA 05.

[31] LI 03B used Ge detector in active shield near nuclear reactor to test for nonstandard $\overline{\nu}_e$-e scattering.

[32] GRIMUS 02 obtain stringent bounds on all Majorana neutrino transition moments from a simultaneous fit of LMA-MSW oscillation parameters and transition moments to global solar neutrino data + reactor data. Using only solar neutrino data, a 90% CL bound of $6.3 \times 10^{-10} \mu_B$ is obtained.

[33] TANIMOTO 00 combined $e^+ e^- \to \nu\overline{\nu}\gamma$ data from VENUS, TOPAZ, and AMY.

[34] AYALA 99 improves the limit of BARBIERI 88.

[35] BEACOM 99 obtain the limit using the shape, but not the absolute magnitude which is affected by oscillations, of the solar neutrino spectrum obtained by Superkamiokande (825 days). This μ_ν can be different from the reactor μ_ν in certain oscillation scenarios.

[36] RAFFELT 99 is an update of RAFFELT 90. This limit applies to all neutrino flavors which are light enough (< 5 keV) to be emitted from globular-cluster red giants. This limit pertains equally to electric dipole moments and magnetic transition moments, and it applies to both Dirac and Majorana neutrinos.

[37] RAFFELT 99 is essentially an update of BERNSTEIN 63, but is derived from the helioseismological limit on a new energy-loss channel of the Sun. This limit applies to all neutrino flavors which are light enough (<1 keV) to be emitted from the Sun. This limit pertains equally to electric dipole and magnetic transition moments, and it applies to both Dirac and Majorana neutrinos.

[38] ACCIARRI 97Q result applies to both direct and transition magnetic moments and for q^2=0.

[39] ELMFORS 97 calculate the rate of depolarization in a plasma for neutrinos with a magnetic moment and use the constraints from a big-bang nucleosynthesis on additional degrees of freedom.

[40] Applies to absolute value of magnetic moment.

[41] DERBIN 93 determine the cross section for 0.6–2.0 MeV electron energy as $(1.28 \pm 0.63) \times \sigma_{\rm weak}$. However, the (reactor on – reactor off)/(reactor off) is only $\sim 1/100$.

[42] COOPER-SARKAR 92 assume $f_{D_s}/f_\pi = 2$ and D_s, $\overline{D}_s$ production cross section = 2.6 μb to calculate ν flux.

[43] VIDYAKIN 92 limit is from a $e\overline{\nu}_e$ elastic scattering experiment. No experimental details are given except for the cross section from which this limit is derived. Signal/noise was 1/10. The limit uses $\sin^2\theta_W = 0.23$ as input.

[44] DORENBOSCH 91 corrects an incorrect statement in DORENBOSCH 89 that the ν magnetic moment is $< 1 \times 10^{-9}$ at the 95%CL. DORENBOSCH 89 measures both $\nu_\mu e$ and $\overline{\nu} e$ elastic scattering and assume $\mu(\nu) = \mu(\overline{\nu})$.

[45] KRAKAUER 90 experiment fully reported in ALLEN 93.

[46] RAFFELT 90 limit applies for a diagonal magnetic moment of a Dirac neutrino, or for a transition magnetic moment of a Majorana neutrino. In the latter case, the same analysis gives $< 1.4 \times 10^{-12}$. Limit at 95%CL obtained from δM_c.

[47] Significant dependence on details of stellar models.

[48] FUKUGITA 88 find magnetic dipole moments of any two neutrino species are bounded by $\mu < 10^{-16}$ [10^{-9} G/B_0] where B_0 is the present-day intergalactic field strength.

[49] GROTCH 88 combined data from MAC, ASP, CELLO, and Mark J.

[50] For m_ν = 8–200 eV. NUSSINOV 87 examines transition magnetic moments for $\nu_\mu \to \nu_e$ and obtain $< 3 \times 10^{-15}$ for $m_\nu > 16$ eV and $< 6 \times 10^{-14}$ for $m_\nu > 4$ eV.

[51] We obtain above limit from SUTHERLAND 76 using their limit $f < 1/3$.

[52] KIM 74 is a theoretical analysis of $\overline{\nu}_\mu$ reaction data.

NEUTRINO CHARGE RADIUS SQUARED

We report limits on the so-called neutrino charge radius squared. While the straight-forward definition of a neutrino charge radius has been proven to be gauge-dependent and, hence, unphysical (LEE 77C), there have been recent attempts to define a physically observable neutrino charge radius (BERNABEU 00, BERNABEU 02). The issue is still controversial (FUJIKAWA 03, BERNABEU 03). A more general interpretation of the experimental results is that they are limits on certain nonstandard contributions to neutrino scattering.

		[8] GRIFOLS	89B	ASTR	SN 1987A

[1] DENIZ 10 observe reactor $\overline{\nu}_e e$ scattering with recoil kinetic energies 3–8 MeV using CsI(Tl) detectors. The observed rate and spectral shape are consistent with the Standard Model prediction, leading to the reported constraint on $\overline{\nu}_e$ charge radius.

[2] CADEDDU 18 use the data of the COHERENT experiment, AKIMOV 18. The limit is $\langle r^2_\nu \rangle$ for ν_μ obtained from the time-dependent data. Weaker limits were obtained for charge radii of ν_e and for transition charge radii. The published value was divided by 2 to conform to the convention of this table.

[3] Based on analysis of CCFR 98 results. Limit is on $\langle r^2_V \rangle + \langle r^2_A \rangle$. The CHARM II and E734 at BNL results are reanalyzed, and weaker bounds on the charge radius squared than previously published are obtained. The NuTeV result is discussed; when tentatively interpreted as ν_μ charge radius it implies $\langle r^2_V \rangle + \langle r^2_A \rangle = (4.20 \pm 1.64) \times 10^{-33}$ cm^2.

[4] Results of LEP-2 are interpreted as limits on the axial-vector charge radius squared of a Majorana ν_τ. Slightly weaker limits for both vector and axial-vector charge radius squared are obtained for the Dirac case, and somewhat weaker limits are obtained from the analysis of lower energy data (LEP-1.5 and TRISTAN).

[5] AUERBACH 01 measure $\nu_e e$ elastic scattering with LSND detector. The cross section agrees with the Standard Model expectation, including the charge and neutral current interference. The 90% CL applies to the range shown.

[6] VIDYAKIN 92 limit is from a $e\overline{\nu}$ elastic scattering experiment. No experimental details are given except for the cross section from which this limit is derived. Signal/noise was 1/10. The limit uses $\sin^2\theta_W = 0.23$ as input.

[7] Result is obtained from reanalysis given in ALLEN 91, followed by our reduction to obtain $1\,\sigma$ errors.

[8] GRIFOLS 89B sets a limit of $\langle r^2 \rangle < 0.2 \times 10^{-32}$ cm^2 for right-handed neutrinos.

Number of Neutrino Types

The neutrinos referred to in this section are those of the Standard SU(2)×U(1) Electroweak Model possibly extended to allow nonzero neutrino masses. Light neutrinos are those with $m < m_Z/2$. The limits are on the number of neutrino mass eigenstates, including ν_1, ν_2, and ν_3.

THE NUMBER OF LIGHT NEUTRINO TYPES FROM COLLIDER EXPERIMENTS

Revised June 2020 by C.-J. Lin (LBNL). Written by D. Karlen (University of Victoria and TRIUMF).

The most precise measurements of the number of light neutrino types, N_ν, come from studies of Z production in e^+e^- collisions. The invisible partial width, $\Gamma_{\rm inv}$, is determined by subtracting the measured visible partial widths, corresponding to Z decays into quarks and charged leptons, from the total Z width. The invisible width is assumed to be due to N_ν light neutrino species each contributing the neutrino partial width Γ_ν as given by the Standard Model. In order to reduce the model dependence, the Standard Model value for the ratio of the neutrino to charged leptonic partial widths, $(\Gamma_\nu/\Gamma_\ell)_{\rm SM} = 1.991 \pm 0.001$, is used instead of $(\Gamma_\nu)_{\rm SM}$ to determine the number of light neutrino types:

$$N_\nu = \frac{\Gamma_{\rm inv}}{\Gamma_\ell}\left(\frac{\Gamma_\ell}{\Gamma_\nu}\right)_{\rm SM} . \qquad (1)$$

The combined result from the four LEP experiments is $N_\nu = 2.984 \pm 0.008$ [1]. Recent analyses applied corrections to the LEP result [1] by including the effect of correlated luminosity systematics and also using an improved Bhabha cross section calculation [2,3] to obtain $N_\nu = 2.9963 \pm 0.0074$.

In the past, when only small samples of Z decays had been recorded by the LEP experiments and by the Mark II at SLC, the uncertainty in N_ν was reduced by using Standard Model fits to the measured hadronic cross sections at several center-of-mass energies near the Z resonance. Since this method is much more dependent on the Standard Model, the approach described above is favored.

Before SLC and LEP, limits on the number of neutrino generations were placed by experiments at lower-energy e^+e^- colliders by measuring the cross section of the process $e^+e^- \to \nu\overline{\nu}\gamma$. The ASP, CELLO, MAC, MARK J, and VENUS experiments observed a total of 3.9 events above background [4], leading to a 95% CL limit of $N_\nu < 4.8$. This process has a much larger cross section at center-of-mass energies near the Z mass and has been measured at LEP by the ALEPH, DELPHI, L3, and OPAL experiments [5]. These experiments have observed several thousand such events, and the combined result is $N_\nu = 3.00 \pm 0.08$. The same process has also been measured by the LEP experiments at much higher center-of-mass energies, between 130 and 208 GeV, in searches for new physics [6]. Combined with the lower energy data, the result is $N_\nu = 2.92 \pm 0.05$.

Experiments at $p\overline{p}$ colliders also placed limits on N_ν by determining the total Z width from the observed ratio of

$W^{\pm} \to \ell^{\pm}\nu$ to $Z \to \ell^{+}\ell^{-}$ events [7]. This involved a calculation that assumed Standard Model values for the total W width and the ratio of W and Z leptonic partial widths, and used an estimate of the ratio of Z to W production cross sections. Now that the Z width is very precisely known from the LEP experiments, the approach is now one of those used to determine the W width.

[1] BRIEDEN 22 combines large scale structure data from BOSS and eBOSS including the shape of the matter power spectrum with Planck CMB data.

[2] KUMAR 22 combine the reconstructed galaxy power spectrum from BOSS data with Planck CMB data.

[3] YEH 22 combines Planck 2018 CMB data with BBN and observations of deuterium and Helium-4. Supersedes FIELDS 20.

[4] AGHANIM 20 best fit on number of neutrino types is based on Planck data combined with lensing and baryon acoustic oscillations (BAO). Without BAO, they find $2.89^{+0.18}_{-0.19}$. Several other values are quoted using different combinations of data.

[5] FIELDS 20 combines Planck 2018 CMB data with BBN and observations of deuterium and Helium-4.

[6] IVANOV 20 combines 2018 Planck CMB data with baryon acoustic oscillation data from BOSS. This study is based on a full-shape likelihood for the redshift-space galaxy power spectrum of the BOSS data.

[7] Uses Planck Data combined with an independent standard measure of distance to the sound horizon to set a limit on the total number of neutrinos. Only CMB and early-time information are used.

[8] CYBURT 16 combines Planck 2015 CMB data with BBN and observations of deuterium and Helium-4.

[9] ROSSI 15 sets limits on the number of neutrino types using BOSS Lyman alpha forest data combined with Planck CMB data and baryon acoustic oscillations.

[10] Fit to the number of neutrino degrees of freedom from Planck CMB data along with WMAP polarization, high L, and BAO data.

[11] Fit to the number of neutrinos degrees of freedom from Planck CMB data along with BAO, shear and cluster data.

[12] Fit based on the SPT-SZ survey combined with CMB, BAO, and H_0 data.

[13] Constrains the number of neutrino degrees of freedom (marginalizing over the total mass) from CMB, CMB lensing, BAO, and galaxy clustering data.

[14] Limit on the number of light neutrino types from observational Hubble parameter data with seven-year WMAP data, SPT, and the most recent estimate of H_0. Best fit is 3.45 ± 0.65.

[15] Limit on the number of light neutrino types from the CFHTLS combined with seven-year WMAP data and a prior on the Hubble parameter. Best fit is $4.17^{+1.62}_{-1.26}$. Limit is relaxed to $3.98^{+2.02}_{-1.20}$ when small scales affected by non-linearities are removed.

[16] Constrains the number of neutrino types from recent CMB and large scale structure data. No priors on other cosmological parameters are used.

[17] Constrains the number of neutrino types from recent CMB, large scale structure, Lyman-alpha forest, and SN1a data. The slight preference for $N_\nu > 3$ comes mostly from the Lyman-alpha forest data.

[18] Constrains the number of neutrino types from recent CMB and large scale structure data. See also HAMANN 07.

[19] Limit on the number of neutrino types based on ^{4}He and D/H abundance assuming a baryon density fixed to the WMAP data. Limit relaxes to 4.6 if D/H is not used or to 5.8 if only D/H and the CMB are used. See also CYBURT 01 and CYBURT 03.

[20] Limit on the number of neutrino types based on combination of WMAP data and big-bang nucleosynthesis. The limit from WMAP data alone is 8.3. See also KNELLER 01. $N_\nu \geq 3$ is assumed to compute the limit.

[21] 95% confidence level range on the number of neutrino flavors from WMAP data combined with other CMB measurements, the 2dfGRS data, and HST data.

[22] SHVARTSMAN 69 limit inferred from his equations.

Double-β Decay

OMITTED FROM SUMMARY TABLE

NEUTRINOLESS DOUBLE-β DECAY

Revised August 2019 by A. Piepke (University of Alabama) and P. Vogel (Caltech) .

Observation of neutrinoless double-beta ($0\nu\beta\beta$) decay would signal violation of total lepton number conservation. The process can be mediated by an exchange of a light Majorana neutrino, or by an exchange of other particles. However, the existence of $0\nu\beta\beta$-decay requires a nonvanishing Majorana neutrino mass, no matter what the actual mechanism is. As long as only a limit on the lifetime is available, limits on the effective Majorana neutrino mass, on the lepton-number violating right-handed current or other possible mechanisms mediating $0\nu\beta\beta$ decay can be obtained, independently of the actual mechanism, by assuming that one of these "new physics" possibilities dominates. These limits are listed in the Double-β Decay Listings of the experimental measurements.

In the following we assume that the exchange of light Majorana neutrinos ($m_{\nu_i} \leq 10$ MeV) contributes dominantly to the decay rate. Besides a dependence on the phase space ($G^{0\nu}$) and the nuclear matrix element ($M^{0\nu}$), the observable $0\nu\beta\beta$-decay rate is proportional then to the square of the effective Majorana mass m_{ee}, $(T^{0\nu}_{1/2})^{-1} = G^{0\nu} \cdot |M^{0\nu}|^2 \cdot m^2_{ee}$, with $m^2_{ee} = |\sum_i U^2_{ei} m_{\nu_i}|^2$. The sum contains, in general, complex CP-phases in U^2_{ei}, i.e., cancellations may occur. For three neutrino flavors there are two physical phases for Majorana neutrinos (η_1, η_2) and one for Dirac neutrinos (δ_{CP}). The relevant Majorana phases affect only processes to which lepton-number changing amplitudes contribute. Given the general 3×3 mixing matrix for Majorana neutrinos, one can construct other analogous lepton number violating quantities, $m_{\ell\ell'} = \sum_i U_{\ell i} U_{\ell' i} m_{\nu_i} (\ell$ or $\ell' \neq e)$. However, these are currently much less constrained than m_{ee}.

Nuclear structure calculations are needed to deduce m_{ee} from the decay rate. While $G^{0\nu}$ can be calculated accurately, the computation of $M^{0\nu}$ is subject to uncertainty. Comparing different nuclear model evaluations indicates a factor ∼2-3 spread in the calculated nuclear matrix elements. Nuclear structure calculation consistently overestimate Gamow-Teller (axial current) matrix elements. This inability of the nuclear models to reproduce Gamow-Teller decay rates is often parametrized in form of a modified coupling constant g_A. Many nuclear theorists interpret this shortcoming as evidence that important physics is missing in the modeling of weak nuclear transitions. It is not clear how these observed uncertainties impact $0\nu\beta\beta$-matrix elements. Nevertheless, this constitutes an additional element of uncertainty. Recent work, [1] shows how the discrepancy between experimental and theoretical axial current matrix elements might be resolved. However, application of this approach to the $0\nu\beta\beta$ decay remains to be accomplished. The particle physics quantities to be determined are thus nuclear model-dependent, so the half-life measurements are listed first. Where possible, we reference the nuclear matrix elements used in the subsequent analysis. Since rates for the conventional $2\nu\beta\beta$ decay serve to constrain the nuclear theory models, results for this process are also given.

Oscillation experiments utilizing atmospheric, accelerator, solar, and reactor produced neutrinos and anti-neutrinos show that at least some neutrinos are massive. However, so far the inverted mass ordering (i.e., whether $\Delta m^2_{31} < 0$) is disfavored only by 2-3 σ compared to the normal mass ordering (when $\Delta m^2_{31} > 0$), while the absolute neutrino mass values or the properties of neutrinos under CPT-conjugation (Dirac or Majorana) remain undetermined. All confirmed oscillation experiments can be consistently described using three interacting neutrino species with two mass splittings and three mixing angles. (For values of the mixing angles and mass square differences see the corresponding tables.)

Based on the 3-neutrino analysis:
$m^2_{ee} = |\cos^2\theta_{13}\cos^2\theta_{12}m_1 + e^{2i(\eta_2-\eta_1)}\cos^2\theta_{13}\sin^2\theta_{12}m_2 + e^{-2i(\eta_1+\delta_{CP})}\sin^2\theta_{13}m_3|^2$, valid for both mass orderings. Given the present knowledge of the neutrino oscillation parameters one can derive a relation between the effective Majorana mass and the mass of the lightest neutrino, as illustrated in Figure 14.11 in the Neutrino Masses, Mixing and Oscillations review. The three mass orderings allowed by the oscillation data: normal ($m_1 < m_2 \ll m_3$), inverted ($m_3 \ll m_1 < m_2$), and degenerate ($m_1 \approx m_2 \approx m_3$), result in different projections. The width of the colored bands reflects the uncertainty introduced by the unknown Majorana and Dirac phases as well as the experimental errors of the oscillation parameters. The latter causes only minor broadening of the bands. Because of the overlap of the different mass scenarios, a measurement of m_{ee} would not reveal which mass ordering is applicable, provided the value of m_{ee} is in the overlapping range.

Analogous plots depict the relation of m_{ee} with the summed neutrino mass $m_{tot} = m_1 + m_2 + m_3$, constrained by observational cosmology, and m_{ee} as a function of the average mass $m^{eff}_{\nu_e} = [\Sigma|U_{ei}|^2 m^2_{\nu_i}]^{1/2}$ determined through the analysis of the electron energy distribution in low energy beta decays. (See Fig. 1 of [2].) The oscillation data thus allow to test whether observed values of m_{ee} and m_{tot} or $m^{eff}_{\nu_e}$ are consistent within the 3 neutrino framework. The rather large intrinsic width of the $\beta\beta$-decay constraints essentially does not allow to positively identify the mass ordering, and thus the sign of Δm^2_{31}, even in combination with these other observables. Naturally, if a value of $0 < m_{ee} \leq 0.01$ eV is ever established, then the normal mass ordering becomes the only possible scenario.

It should be noted that systematic uncertainties of the nuclear matrix elements and possible quenching of the axial current matrix elements are sometimes not folded into the mass limits reported by $\beta\beta$-decay experiments. Taking this additional uncertainty into account would further widen the projections. The plots are based on a 3-neutrino analysis. If it turns out that additional, i.e. sterile light neutrinos exist, the allowed regions would be modified substantially.

If neutrinoless double-beta decay is observed, it will be possible to fix a range of absolute values of the masses m_{ν_i}. Unlike the direct neutrino mass measurements, however, a limit on m_{ee} does not allow one to constrain the individual mass values m_{ν_i} even when the mass differences Δm^2_{ij} are known.

Neutrino oscillation data imply the existence of a lower limit ~ 0.014 eV for the Majorana neutrino mass for the inverted mass ordering pattern, while m_{ee} could, by fine tuning, vanish in the case of the normal mass ordering. Several new double-beta searches have been proposed to probe the interesting m_{ee} mass range, with the prospect of full coverage of the inverted mass ordering region within the next decade.

The $0\nu\beta\beta$ decay mechanism discussed so far is not the only way in which the decay can occur. Numerous other possible scenarios have been proposed, however, all of them requiring new physics. It will be a challenging task to decide which mechanism was responsible once $0\nu\beta\beta$ decay is observed. LHC experiments may reveal corresponding signatures for new physics of lepton number violation. If lepton-number violating right-handed weak current interactions exist, its strength can be characterized by the phenomenological coupling constants η and λ (η describes the coupling between the right-handed lepton current and left-handed quark current while λ describes the coupling when both currents are right-handed). The $0\nu\beta\beta$ decay rate then depends on $\langle\eta\rangle = \eta\sum_i U_{ei}V_{ei}$ and $\langle\lambda\rangle = \lambda\sum_i U_{ei}V_{ei}$ that vanish for massless or unmixed neutrinos ($V_{\ell j}$ is a matrix analogous to $U_{\ell j}$ but describing the mixing with the hypothetical right-handed neutrinos). The observation of the single electron spectra could, in principle, allow to distinguish this mechanism of $0\nu\beta\beta$ from the light Majorana neutrino exchange driven mode. The limits on $\langle\eta\rangle$ and $\langle\lambda\rangle$ are listed in a separate table. The reader is cautioned that a number of earlier experiments did not distinguish between η and λ. In addition, see the section on Majoron searches for additional limits set by these experiments.

Half-life 0ν double-β decay

In most cases the transitions (Z,A) $\rightarrow$ (Z+2,A) + $2e^-$ to the 0^+ ground state of the final nucleus are listed. We also list transitions that decrease the nuclear charge ($2e^+$, e^+ CC and double EC) and transitions to an excited state of the final nucleus (0^+_i, 2^+, and 2^+_i). In the following Listings only the best or comparable limits for the half-lives of each transition are reported and only those with about $T_{1/2} > 10^{23}$ years that are relevant for particle physics.

[1] ABE 23 use the combined data set of the KamLAND-Zen 400 and 800 experiments, utilizing 745 kg of isotopically enriched xenon (90.9% ^{136}Xe), dissolved in liquid scintillator and an exposure of 970 kg·yr of ^{136}Xe, to derive this limit on $0\nu\beta\beta$ decay. A half-life sensitivity of 1.5×10^{26} yr is reported.

[2] ARNQUIST 23 use the final data set of the MAJORANA DEMONSTRATOR experiment, operating enriched in ^{76}Ge detectors, to set this limit on the $0\nu\beta\beta$ half-life of ^{76}Ge. The exposure is 64.5 kg·yr. A median sensitivity of 8.1×10^{25} yr is reported.

[3] AUGIER 23 utilize the complete data, set collected by the CUPID-Mo bolometric calorimeter with particle ID and located at the LSM, to study various double beta decays of ^{100}Mo to excited states of the daughter nucleus. An exposure of 1.47 kg·yr of ^{100}Mo is available.

[4] NOVELLA 23 use data collected by the NEXT-White experiment to limit the $0\nu\ \beta\beta$ half-life of ^{136}Xe. The experiment contains 3.5 kg of enriched Xe and is based on a high-pressure gas TPC. Two different limits are reported, based on different data analysis approaches, $> 5.5 \times 10^{23}$ yr and $> 13 \times 10^{23}$ yr.

[5] ADAMS 22A use the CUORE TeO_2 experiment with an exposure of 288.8 kg·yr of ^{130}Te to place a limit on its $0\nu\ \beta\beta$ decay. The median sensitivity is reported as 280×10^{23} yr. Superseeds ADAMS 20A.

[6] ADAMS 22B use the CUORE bolometric calorimeter to place a limit on the $0\nu\beta\beta$ decay half-life of ^{128}Te.

[7] APRILE 22A use 36.16 kg·yr of ^{136}Xe exposure of the XENON1T not enriched detector to establish the stated limit.

[8] AUGIER 22 use the final data set of the CUPID-Mo cryogenic calorimeter, utilizing enriched $Li_2{}^{100}MoO_4$ and an isotope exposure of 1.47 kg·y, to place a limit on the $0\nu\beta\beta$ decay half-life.

[9] AZZOLINI 22 use the CUPID-0 scintillating cryogenic bolometer to set a limit on the $0\nu\beta\beta$ half-life of ^{82}Se. The analyzed isotope exposure is 8.82 kg·yr. A median sensitivity of 7×10^{24} yr is reported. Supersedes AZZOLINI 19.

[10] AZZOLINI 22 use CUPID-0 data with an isotope exposure of 8.82 kg·yr to set a limit on the $0\nu\beta\beta$ decay to the first excited 0^+ state.

[11] AZZOLINI 22 use CUPID-0 data with an isotope exposure of 8.82 kg·yr to set a limit on the $0\nu\beta\beta$ decay to the first excited 2^+ state.

[12] AZZOLINI 22 use CUPID-0 data with an isotope exposure of 8.82 kg·yr to set a limit on the $0\nu\beta\beta$ decay to the second excited 2^+ state.

[13] ADAMS 21A et al. used 101.76 kg yr of ^{130}Te exposure of the CUORE (LNGS) bolometric detector to place a limit on the decay to the first excited state of ^{130}Xe, superseding ALDUINO 19 as the most restrictive bound on this particular decay.

[14] ARMENGAUD 21 use the CUPID-Mo 4.2 kg array of enriched $Li_2{}^{100}MoO_4$ scintillating bolometers, with 1.17 kg·yr exposure, to set this limit.

[15] ARNQUIST 21 use the MAJORANA demonstrator to set this limit for the $0\nu\ \beta\beta$ decay to the first excited 0^+ state, with a 41.9 kg yr isotopic exposure. The median sensitivity is 39.9×10^{23} yr.

[16] ARNQUIST 21 use the MAJORANA demonstrator to set this limit for the $0\nu\ \beta\beta$ decay to the first excited 2^+ state, with a 41.9 kg yr isotopic exposure. The median sensitivity is 21.2×10^{23} yr.

[17] ARNQUIST 21 use the MAJORANA demonstrator to set this limit for the $0\nu\ \beta\beta$ decay to the second excited 2^+ state, with a 41.9 kg yr isotopic exposure. The median sensitivity is 18.6×10^{23} yr.

[18] ADAMS 20A use the CUORE detector to search for the $0\nu\ \beta\beta$ decay of ^{130}Te. The exposure was 372.5 kg·yr of TeO_2 corresponding to 103.6 kg·yr of ^{130}Te. The exclusion sensitivity is 1.7×10^{25}yr. Supersedes ALDUINO 18.

[19] AGOSTINI 20B present the final data set of the GERDA experiment, searching for $0\nu\ \beta\beta$ decay of ^{76}Ge with isotopically enriched, high resolution Ge detectors. A final exposure of 127.2 kg·yr is reported. The experiment reports the lowest background and longest half life limit ever achieved by any double beta decay experiment. The reported experiment sensitivity equals the limit. Supersedes AGOSTINI 19.

[20] ALDUINO 19 use the combined data of the CUORICINO and CUORE-0 experiments to place a lower limit on the half life of the $0\nu\ \beta\beta$ decay of ^{130}Te to the first excited 0^+ state of ^{130}Xe. Supersedes ANDREOTTI 12.

[21] ALENKOV 19 report the $0\nu\ \beta\beta$ decay half-life limit based on the 52.1 kg·d exposure of ^{100}Mo, of a a cryogenic dual heat and light detector in the Yangyang underground laboratory. The median sensitivity is 1.1×10^{23} years.

[22] ANTON 19 uses he complete dataset of the EXO-200 detector to search for the $0\nu\ \beta\beta$ decay. The exposure is 234.1 kg yr. The median sensitivity is 5.0×10^{25} yr. Supersedes ALBERT 18 and ALBERT 14B.

[23] NI 19 use the PandaX-II dual phase TPC at CJPL to search for the $0\nu\ \beta\beta$ decay of ^{136}Xe. The half-life limit 2.4×10^{23} yr is obtained from 22.2 kg yr exposure with a sensitivity of 1.9×10^{23} yr.

[24] ALDUINO 18 uses the CUORE detector to search for the $0\nu\ \beta\beta$ decay of ^{130}Te. The exposure is 86.3 kg·year of natural TeO_2 corresponding to 24.0 kg·year for ^{130}Te. The median sensitivity is 0.7×10^{25} yr. The limit is obtained combining the new data from CUORE with those of CUORE0 (9.8 kg·year of ^{130}Te) and Cuoricino (19.8 kg·year of ^{130}Te).

[25] ARNOLD 18 use the NEMO-3 tracking detector to place a limit on the $0\nu\beta\beta$ decay of ^{82}Se. This is a slightly weaker limit than in BARABASH 11A, using the same detector. Supersedes ARNOLD 05A.

[26] BARABASH 18 use 1.162 kg of $^{116}CdWO_4$ scintillating crystals to obtain this limit. Supersedes DANEVICH 03 with analogous source and is more sensitive than ARNOLD 17.

[27] ALBERT 17C uses the EXO-200 detector that contains 19.098 $\pm$ 0.014% admixture of ^{134}Xe to search for the 0ν and $2\nu\ \beta\beta$ decay modes. The exposure is 29.6 kg·year. The median sensitivity is 1.9×10^{21} years.

[28] ARNOLD 17 use the NEMO-3 tracking calorimeter, containing 410 g of enriched ^{116}Cd exposed for 5.26 yr, to determine the half-life limit. Supersedes BARABASH 11A.

[29] ALDUINO 16 report result obtained with 9.8 kg·y of data collected with the CUORE-0 bolometer, combined with data from the CUORICINO. Supersedes ALFONSO 15.

[30] ASAKURA 16 use the KamLAND-Zen liquid scintillator calorimeter (^{136}Xe 89.5 kg yr) to place a limit on the $0\nu\beta\beta$-decay into the first excited state of the daughter nuclide.

[31] ASAKURA 16 use the KamLAND-Zen liquid scintillator calorimeter (^{136}Xe 89.5 kg yr) to place a limit on the $0\nu\beta\beta$-decay into the second excited state of the daughter nuclide.

[32] ASAKURA 16 use the KamLAND-Zen liquid scintillator calorimeter (^{136}Xe 89.5 kg yr) to place a limit on the $0\nu\beta\beta$-decay into the third excited state of the daughter nuclide.

[33] ARNOLD 15 use the NEMO-3 tracking calorimeter with 34.3 kg yr exposure to determine the limit of $0\nu\beta\beta$-half life of ^{100}Mo. Supersedes ARNOLD 2005A and BARABASH 11A.

[34] ANDREOTTI 12 use high resolution TeO_2 bolometric calorimeter to search for the $0\nu\beta\beta$ decay of ^{130}Te leading to the excited 0^1_+ state at 1793.5 keV.

[35] UMEHARA 08 use CaF_2 scintillation calorimeter to search for double beta decay of ^{48}Ca. Limit is significantly more stringent than quoted sensitivity: 18×10^{21} years.

[36] Limit on 0ν-decay to the first excited 0^+_1-state of daughter nucleus using NEMO-3 tracking calorimeter. Supersedes DASSIE 95.

[37] Limit on 0ν-decay to the first excited 2^+-state of daughter nucleus using NEMO-3 tracking calorimeter.

[38] Supersedes ALESSANDRELLO 00. Array of TeO_2 crystals in high resolution cryogenic calorimeter. Some enriched in ^{128}Te. Ground state to ground state decay.

[39] Limit on $0\nu\beta\beta$ decay of ^{116}Cd using enriched $CdWO_4$ scintillators. Supersedes DANEVICH 00.

[40] AALSETH 02B limit is based on 117 mol·yr of data using enriched Ge detectors. Background reduction by means of pulse shape analysis is applied to part of the data set. Reported limit is slightly less restrictive than that in KLAPDOR-KLEINGROTHAUS 01 However, it excludes part of the allowed half-life range reported in KLAPDOR-KLEINGROTHAUS 01B for the same nuclide. The analysis has been criticized in KLAPDOR-KLEINGROTHAUS 04B. The criticism was addressed and disputed in AALSETH 04.

Half-life measurements of the two-neutrino double-β decay

The measured half-life values for the transitions (Z,A) $\rightarrow$ (Z+2,A) + $2e^-$ + $2\overline{\nu}_e$ to the 0^+ ground state of the final nucleus are listed. We also list the transitions to an excited state of the final nucleus (0^+_i, etc.). We report only the measuremetnts with the smallest (or comparable) uncertainty for each transition.

[1] AGOSTINI 23 report an updated value for the $2\nu\ \beta\beta$ half-life of ^{76}Ge; the final result of the GERDA Phase II experiment. A subset of the data, corresponding to an exposure of exposure is 11.8 kg·yr, is utilized. This is one of the most precise measurements of $2\nu\ \beta\beta$ decay reported in the literature. An effective nuclear matrix element of 0.101 ± 0.001 is derived from this result.

[2] AGUERRE 23 report the results of a 5.25 yr search for the $2\nu\ \beta\beta$ decay to the exited $0^+ \to 0^+_1$ state of the daughter nucleus, using the NEMO-3 tracking calorimeter. 36.6g of ^{150}Nd isotope were available for the measurement of this decay rate.

[3] AUGIER 23 utilize the complete data, set collected by the CUPID-Mo bolometric calorimeter with particle ID and located at the LSM, to measure the ^{100}Mo $2\nu\beta\beta$ half-life to excited 0^+_1 state of the daughter nucleus. An exposure of 1.47 kg·yr of ^{100}Mo is available.

[4] AUGIER 23A use full data set collected by the CUPID-Mo experiment to derive an improved $2\nu\ \beta\beta$ g.s. to g.s. half-life of ^{100}Mo. An exposure of 1.48 kg·yr of ^{100}Mo is utilized. Supersedes ARMENGAUD 20 .

[5] AZZOLINI 23A report an improved measurement of the $2\nu\ \beta\beta$ decay with an exposure of 8.82 kg·yr of ^{82}Se, collected with the CUPID-0 detector. Superseded AZZOLINI 19B.

[6] NOVELLA 23 used the NEXT-White experiment, with a fiducial mass of 3.5 kg of enriched xenon, to measure the $2\nu\ \beta\beta$ g.s. to g.s. half-life of ^{136}Xe. The experiment is based on a high-pressure gas TPC. Supersedes NOVELLA 22.

[7] ADAMS 22B derive the $2\nu\beta\beta$ half-life of ^{128}Te from data of the CUORE bolometric calorimeter and the half-live ratio for ^{130}Te / ^{128}Te reported in BERNATOWICZ 92.

[8] APRILE 22A report an improved ^{124}Xe 2νDEC half-life measurement for ^{124}Xe, using data collected by the XENON1T detector with an isotopically not enriched Xe target. The analyzed ^{124}Xe exposure is 0.87 kg·yr. The statistical significance of the signal is 7.0 sigma. The stated half-life considers captures from the K shell up to the N5 shell.This result supersedes APRILE 19E, which exclusively considered captures from the K shell.

[9] APRILE 22B use data collected by the XENONnT dark matter experiment to derive an improved ^{124}Xe 2νDEC half-life measurement for ^{124}Xe. This result supersedes APRILE 22A.

[10] NOVELLA 22 report on a high-pressure gas TPC at Canfranc underground laboratory, filled with 3.5 kg (fiducial) xenon gas, used to measure the $2\nu\ \beta\beta$ decay of ^{136}Xe. Topological track reconstruction is utilized in the data analysis. The measurement is based on comparing runs with isotopically enriched and depleted xenon. Other measurements with smaller error exist.

[11] ADAMS 21 use 102.7 kg yr of ^{130}Te exposure, collected by the CUORE bolometric detector at LNGS, to perform a measurement of the $2\nu\ \beta\beta$ decay of ^{130}Te. The dataset is more than 10-times that collected by the CUORE-0 experiment. The result has been revised in ADAMS 23A. Supersedes ALDUINO 17.

[12] APRILE 19E report first measurement of two-neutrino double electron capture in ^{124}Xe using the XENON1T detector with a 0.73 t-yr exposure. An excess of 126 ± 29 events is observed at 64.3 ± 0.6 keV decay energy, corresponding to $\sqrt{\Delta\chi^2} = 4.4$ with respect to the background-only hypothesis.

[13] ARNOLD 19 use the NEMO-3 tracking calorimeter with 34.3 kg y exposure to determine the $2\nu\ \beta\beta$ half-life of ^{100}Mo. Supersedes ARNOLD 15.

[14] ARNOLD 18 use the NEMO-3 tracking detector to determine the $2\nu\,\beta\beta$ half-life of ^{82}Se. 0.93 kg of ^{82}Se was observed for 5.25 y. The half-life value was obtained based on the single-state-dominance (SSD) hypothesis, preferred in this case by about 2 σ. Supersedes ARNOLD 05A.

[15] BARABASH 18 use 1.162 kg of $^{116}CdWO_4$ scintillating crystals to obtain this value. Supersedes DANEVICH 03 with analogous source and agrees with ARNOLD 17 with the NEMO-3 detector.

[16] ALBERT 17C uses the EXO-200 detector that contains $19.098 \pm 0.014\%$ admixture of ^{134}Xe to search for the $2\nu\ \beta\beta$ decay mode. The exposure is 29.6 kg·year. The median sensitivity is 1.2×10^{21} years.

[17] ALDUINO 17 use the CUORE-0 detector containing 10.8 kg of ^{130}Te in 52 crystals of TeO_2. The exposure was 9.3 kg yr of ^{130}Te. This is a more accurate rate determination than in ARNOLD 11 and BARABASH 11A.

[18] ARNOLD 17 use the NEMO-3 tracking calorimeter, containing 410 grams of enriched ^{116}Cd exposed for 5.26 years, to determine the half-life value.

[19] ARNOLD 16 use the NEMO-3 detector and a source of 6.99 g of ^{48}Ca. The half-life is based on 36.7 g year exposure. It is consistent, although somewhat longer, than the previous determinations of the half-life. Supersedes BARABASH 11A.

[20] ARNOLD 16A use the NEMO-3 tracking calorimeter, containing 36.6 g of ^{150}Nd exposed for 1918.5 days, to determine the half-life. Supersedes ARGYRIADES 09.

[21] AGOSTINI 15A use 17.9 kg yr exposure of the GERDA calorimeter to derive an improved measurement of the $2\nu\beta\beta$ decay half life of ^{76}Ge.

[22] ARNOLD 15 use the NEMO-3 tracking calorimeter with 34.3 kg yr exposure to determine the $2\nu\beta\beta$-half life of ^{100}Mo. Supersedes ARNOLD 05A and ARNOLD 04.

[23] ALBERT 14 use the EXO-200 tracking detector for a re-measurement of the $2\nu\beta\beta$-half life of ^{136}Xe. A nuclear matrix element of 0.0218 ± 0.0003 MeV^{-1} is derived from this data. Supersedes ACKERMAN 11.

[24] GAVRILYAK 13 use a proportional counter filled with Kr gas to search for the 2ν2K decay of ^{78}Kr. Data with the enriched and depleted Kr were used to determine signal and background. A 2.5σ excess of events obtained with the enriched sample is interpreted as an indication for the presence of this decay.

[25] GANDO 12A use a modification of the existing KamLAND detector. The $\beta\beta$ decay source/detector is 13 tons of enriched ^{136}Xe-loaded scintillator contained in an inner balloon. The $2\nu\beta\beta$ decay rate is derived from the fit to the spectrum between 0.5 and 4.8 MeV. This result is in agreement with ACKERMAN 11.

[26] ARNOLD 11 use enriched ^{130}Te in the NEMO-3 detector to measure the $2\nu\ \beta\beta$ decay rate. This result is in agreement with, but more accurate than ARNABOLDI 03.

[27] ARGYRIADES 10 use 9.4 ± 0.2 g of ^{96}Zr in NEMO-3 detector and identify its $2\nu\beta\beta$ decay. The result is in agreement and supersedes ARNOLD 99.

[28] BELLI 10 use enriched ^{100}Mo with 4 HP Ge detectors to record the 590.8 and 539.5 keV γ rays from the decay of the 0^+_1 state in ^{100}Ru both in singles and coincidences. This result confirms the measurement of KIDD 09 and ARNOLD 07 and supersedes them.

[29] First exclusive measurement of 2ν-decay to the first excited 0^+_1-state of daughter nucleus. ARNOLD 07 use the NEMO-3 tracking calorimeter to detect all particles emitted in decay. Result agrees with the inclusive ($0\nu + 2\nu$) measurement of DEBRAECKELEER 01.

[30] ARNOLD 05A use the NEMO-3 tracking detector to determine the $2\nu\beta\beta$ half-life of ^{82}Se with high statistics and low background (389 days of data taking). Supersedes ARNOLD 04.

[31] DANEVICH 03 is calorimetric measurement of $2\nu\beta\beta$ ground state decay of ^{116}Cd using enriched$CdWO_4$ scintillators. Agrees with EJIRI 95 and ARNOLD 96. Supersedes DANEVICH 00.

$\langle m_{ee} \rangle$, The Effective Weighted Sum of Majorana Neutrino Masses Contributing to Neutrinoless Double-β Decay

$\langle m_{ee} \rangle = |\Sigma U^2_{ei} m_{\nu_i}|$, i = 1,2,3. It is assumed that ν_i are Majorana particles and that the transition is dominated by the known (light) neutrinos. Note that U^2_{ei} and not $|U_{ei}|^2$ occur in the sum, and that consequently cancellations are possible. The experiments obtain the limits on $\langle m_\nu \rangle$ from the measured ones on $T_{1/2}$ using a range of nuclear matrix elements (NME), which is reflected in the spread of $\langle m_\nu \rangle$. Different experiments may choose different NME. All assume $g_A = 1.27$. In the following Listings, only the best or comparable limits for each isotope are reported. When not mentioned explicitly the transition is between ground states, but transitions between excited states are also reported.

[1] ABE 23 utilize 745 kg of ^{136}Xe isotope exposure from the combined data set of the KamLAND-Zen 400 and 800 to derive a limit on $\langle m_{\beta\beta}\rangle$. The range reflects the author's assessment of the variability of the theoretically calculated nuclear matrix elements.

[2] ARNQUIST 23 use the final data set of the MAJORANA DEMONSTRATOR experiment, with 64.5 kg·yr of isotop exposure, to derive an upper limit for $\langle m_{\beta\beta}\rangle$. The range reflects the author's assessment of the variability of the theoretically calculated nuclear matrix elements.

[3] NOVELLA 23 use data collected with the NEXT-White experiment to derive a range of upper limits for $\langle m_{\beta\beta}\rangle$. The range reflects the author's assessment of the variability of the theoretically calculated nuclear matrix elements and both half-life limits stated in NOVELLA 23.

[4] ADAMS 22A use 1038.4 kg·yr of TeO_2 exposure collected by the CUORE experiment to determine this range of limits. The range reflects the uncertainty of nuclear matrix element calculations needed for the conversion of half-life to neutrino mass.

[5] APRILE 22A use data taken with the XENON1T detector to limit the Majorana neutrino mass. 36.16 kg·yr of ^{136}Xe exposure were utilized. The reported range of limits is due to uncertainties in the nuclear matrix elements.

[6] AUGIER 22 use the final data set of the CUPID-Mo cryogenic calorimeter with an isotop exposure of 1.47 kg·y to derive a range of neutrino mass limits. The range reflects the authors' estimate of the spread of nuclear matrix element calculations.

[7] AZZOLINI 22 use 8.82 kg·yr of isotopic exposure of the CPID-0 scintillating cryogenic bolometer to set this range of neutrino mass limits. The range reflects the authors' estimate of the spread of nuclear matrix element calculations.

[8] ARMENGAUD 21 use the CUPID-Mo demonstrator, with 1.17 kg·yr exposure of ^{100}Mo, to set this limit. The range reflects the estimated uncertainty of the calculated nuclear matrix elements.

[9] ADAMS 20A use the data of CUORE (372.5 kg·yr exposure of TeO_2) to obtain this limit.

[10] AGOSTINI 20B use the final data set of the GERDA experiment, representing an exposure of 127.2 kg·yr to derive an upper limit for $\langle m_{\beta\beta}\rangle$. Isotopically enriched Ge detectors were used. The range reflects the variability of the theoretically calculated nuclear matrix elements. Supersedes AGOSTINI 19.

[11] ALENKOV 19 report the range of the effective masses $\langle m_{\beta\beta}\rangle$ corresponding to the 0ν $\beta\beta$ decay half-life limit. It is based on the 52.1 kg·d exposure of ^{100}Mo, in the Yangyang underground laboratory. The median sensitivity is 1.1×10^{23} years. The range of $\langle m_{\beta\beta}\rangle$ reflects the uncertainty of nuclear matrix elements.

[12] ANTON 19 uses the complete dataset of the EXO-200 experiment to obtain these limits. The spread reflect the uncertainty in the nuclear matrix elements. Supersedes ALBERT 18 and ALBERT 14B.

[13] NI 19 use the PandaX-II dual phase TPC at CJPL to search for the 0ν $\beta\beta$ decay of ^{136}Xe with 22.2 kg yr exposure. The range in the $m_{\beta\beta}$ limit of 1.3–3.5 eV reflects the range of the calculated nuclear matrix elements. The sensitivity is 1.9×10^{23} yr.

[14] ALDUINO 18 use the combined data of CUORE, CUORE0, and Cuoricino to obtain this limit.

[15] ARNOLD 18 use the NEMO-3 tracking detector to constrain the $0\nu\beta\beta$ decay of ^{82}Se. The limit on $\langle m_{\beta\beta}\rangle$ is obtained assuming light neutrino exchange; the range reflects different calculations of the nuclear matrix elements. This is a somewhat weaker limit than in BARABASH 11A using the same detector.

[16] BARABASH 18 use 1.162 kg of $^{116}CdWO_4$ scintillating crystals to obtain these limits. The spread reflects the estimated uncertainty in the nuclear matrix element. Supersedes DANEVICH 03.

[17] ARNOLD 17 utilize NEMO-3 data, taken with enriched ^{116}Cd to limit the effective Majorana neutrino mass. The reported range results from the use of different nuclear matrix elements. Supersedes BARABASH 11A.

[18] ALDUINO 16 place a limit on the effective Majorana neutrino mass using the combined data of the CUORE-0 and CUORICINO experiments. The range reflects the authors' evaluation of the variability of the nuclear matrix elements. Supersededs ALFONSO 15.

[19] ARNOLD 16A limit is derived from data taken with the NEMO-3 detector and ^{150}Nd. A range of nuclear matrix elements that include the effect of nuclear deformation have been used. Supersedes ARGYRIADES 09.

[20] ARNOLD 15 use the NEMO-3 tracking calorimeter with 34.3 kg yr exposure to determine the neutrino mass limit based on the $0\nu\beta\beta$-half life of ^{100}Mo. The spread range reflects different nuclear matrix elements. Supersedes ARNOLD 14 and BARABASH 11A.

[21] ARGYRIADES 10 use ^{96}Zr and the NEMO-3 tracking detector to obtain the reported mass limit. The range reflects the fluctuation of the nuclear matrix elements considered.

[22] Limit was obtained using CaF_2 scintillation calorimeter to search for double beta decay of ^{48}Ca. Reported range of limits reflects spread of QRPA and SM matrix element calculations used. Supersedes OGAWA 04.

[23] Limit for $\langle m_{\nu}\rangle$ is based on the nuclear matrix elements of STAUDT 90 and ARNOLD 96. Supersedes DANEVICH 00.

Limits on Lepton-Number Violating ($V+A$) Current Admixture

For reasons given in the discussion at the beginning of this section, we list only results from 1989 and later. $\langle\lambda\rangle = \lambda\sum U_{ej}V_{ej}$ and $\langle\eta\rangle = \eta\sum U_{ej}V_{ej}$, where the sum is over the number of neutrino generations. This sum vanishes for massless or unmixed neutrinos. In the following Listings, only best or comparable limits or lifetimes for each isotope are reported.

[1] ARNOLD 18 use the NEMO03 tracking detector, with 0.93 kg of ^{82}Se mass and 5.25 y exposure to obtain the limits for the hypothetical right-handed currents. Supersedes ARNOLD 05A.

[2] BARABASH 18 use 1.162 kg of $^{116}CdWO_4$ scintillating crystals to obtain this limits for the hypothetical right-handed currents in the $0\nu\beta\beta$ decay of ^{116}Cd.

[3] ARNOLD 14 is based on 34.7 kg yr of exposure of the NEMO-3 tracking calorimeter. The reported range limit on $\langle\lambda\rangle$ and $\langle\eta\rangle$ reflects the nuclear matrix element uncertainty in ^{100}Mo.

[4] ARNOLD 07 use NEMO-3 half life limit for 0ν-decay of ^{100}Mo to the first excited 2^+-state of daughter nucleus to limit the right-right handed admixture of weak currents $\langle\lambda\rangle$. This limit is not competitive when compared to the decay to the ground state.

[5] Re-analysis of data originally published in KLAPDOR-KLEINGROTHAUS 04A. Modified pulse shape analysis leads the authors to claim 6σ statistical evidence for observation of 0ν-decay. Authors use matrix element of MUTO 89 to determine $\langle\lambda\rangle$ and $\langle\eta\rangle$. Uncertainty of nuclear matrix element is not reflected in stated errors.

[6] ARNOLD 05A derive limit for $\langle\lambda\rangle$ based on ^{100}Mo data collected with NEMO-3 detector. No limit for $\langle\eta\rangle$ is given. Supersedes ARNOLD 04.

[7] ARNOLD 05A derive limit for $\langle\lambda\rangle$ based on ^{82}Se data collected with NEMO-3 detector. No limit for $\langle\eta\rangle$ is given. Supersedes ARNOLD 04.

[8] ARNOLD 04 use the matrix elements of SUHONEN 94 to obtain a limit for $\langle\lambda\rangle$, no limit for $\langle\eta\rangle$ is given. This limit is more stringent than the limit in EJIRI 01 for the same nucleus.

[9] ARNOLD 04 use the matrix elements of TOMODA 91 and SUHONEN 91 to obtain a limit for $\langle\lambda\rangle$, no limit for $\langle\eta\rangle$ is given.

[10] Supersedes ALESSANDRELLO 00. Cryogenic calorimeter search. Reported a range reflecting uncertainty in nuclear matrix element calculations.

[11] Limits for $\langle\lambda\rangle$ and $\langle\eta\rangle$ are based on nuclear matrix elements of STAUDT 90. Supersedes DANEVICH 00.

[12] The range of the reported $\langle\lambda\rangle$ and $\langle\eta\rangle$ values reflects the spread of the nuclear matrix elements. On axis value assuming $\langle m_{\nu}\rangle$=0 and $\langle\lambda\rangle$=$\langle\eta\rangle$=0, respectively.

[13] GUENTHER 97 limits use the matrix elements of STAUDT 90. Supersedes BALYSH 95 and BALYSH 92.

[14] VUILLEUMIER 93 uses the matrix elements of MUTO 89. Based on a half-life limit 2.6×10^{23} y at 90%CL.

[15] BERNATOWICZ 92 takes the measured geochemical decay width as a limit on the 0ν width, and uses the SUHONEN 91 coefficients to obtain the least restrictive limit on η. Further details of the experiment are given in BERNATOWICZ 93.

Neutrino Mixing

With the possible exceptions of "short-baseline anomalies," such as LSND, all neutrino data can be described within the framework of a 3×3 mixing matrix between the mass eigenstates ν_1, ν_2, and ν_3, leading to the flavor eigenstates ν_e, ν_μ, and ν_τ, as described in the review *"Neutrino masses, mixing and oscillations."*

The Listings are divided in the following sections:

(A) Neutrino fluxes and event ratios: shows measurements which correspond to various oscillation tests for Accelerator, Reactor, Atmospheric, and Solar neutrino experiments. Typically, ratios involve a measurement in a realm sensitive to oscillations compared to one for which no oscillation effect is expected.

(B) Neutrino mixing parameters: shows measurements of $\sin^2(\theta_{12})$, $\sin^2(\theta_{23})$, $\sin^2(\theta_{13})$, Δm^2_{21}, Δm^2_{32}, and δ_{CP} as extracted from the measured data in the quoted publications in the frame of the three-neutrino mixing scheme. The quoted averages are not the result of a global fit, as in the review *"Neutrino masses, mixing, and oscillations,"* and, as a consequence, might slightly differ from them. In some cases, measurements depend on the mass order (normal when $\Delta m^2_{32} > 0$ or inverted when $\Delta m^2_{32} < 0$) or octant of θ_{23} (lower when $\theta_{23} < 45°$ or upper when $\theta_{23} > 45°$).

(C) Other neutrino mixing results:

The LSND anomaly [AGUILAR 01], reported a signal which is consistent with $\overline{\nu}_\mu \to \overline{\nu}_e$ oscillations. In a three neutrino framework, this would be a measurement of θ_{12} and Δm^2_{21}. This does not appear to be consistent with the interpretation of other neutrino data. It has been interpreted as evidence for a 4th "sterile" neutrino. The following listings include results which might be relevant towards understanding this observation. They include searches for $\nu_\mu \to \nu_e$, $\overline{\nu}_\mu \to \overline{\nu}_e$, sterile neutrino oscillations, and others.

(A) Neutrino fluxes and event ratios

Events (observed/expected) from accelerator ν_μ experiments.

Some neutrino oscillation experiments compare the flux in two or more detectors. This is usually quoted as the ratio of the event rate in the far detector to the expected rate based on an extrapolation from the near detector in the absence of oscillations.

VALUE	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
1.01 ± 0.10	[1] ABE	14B	T2K	ν_e rate in T2K near detect.
0.71 ± 0.08	[2] AHN	06A	K2K	K2K to Super-K
0.64 ± 0.05	[3] MICHAEL	06	MINS	All charged current events
$0.71^{+0.08}_{-0.09}$	[4] ALIU	05	K2K	KEK to Super-K
$0.70^{+0.10}_{-0.11}$	[5] AHN	03	K2K	KEK to Super-K

[1] The rate of ν_e from μ decay was measured to be 0.68 ± 0.30 compared to the predicted flux. From K decay 1.10 ± 0.14 compared to the predicted flux.

[2] Based on the observation of 112 events when $158.1^{+9.2}_{-8.6}$ were expected without oscillations. Including not only the number of events but also the shape of the energy distribution, the evidence for oscillation is at the level of about 4.3 σ. Supersedes ALIU 05.

[3] This ratio is based on the observation of 215 events compared to an expectation of 336 ± 14 without oscillations. See also ADAMSON 08.

[4] This ratio is based on the observation of 107 events at the far detector 250 km away from KEK, and an expectation of 151^{+12}_{-10}.

[5] This ratio is based on the observation of 56 events with an expectation of $80.1^{+6.2}_{-5.4}$.

Events (observed/expected) from reactor $\overline{\nu}_e$ experiments.

The quoted values are the ratios of the measured reactor $\overline{\nu}_e$ event rate at the quoted distances, and the rate expected without oscillations. The expected rate is based on the experimental data for the most significant reactor fuels (^{235}U, ^{239}Pu, ^{241}Pu) and on calculations for ^{238}U.

A recent re-evaluation of the spectral conversion of electron to $\overline{\nu}_e$ in MUELLER 11 results in an upward shift of the reactor $\overline{\nu}_e$ spectrum by 3% and, thus, might require revisions to the ratios listed in this table.

0.89 ± 0.15	[11] BOEHM	80		$\overline{\nu}_e p \to e^+ n$

[1] ALMAZAN 20 use the RHF research reactor at ILL to compare their measured anti-neutrino event rate to the calculation by HUBER 11. Reported $0.948 \pm 0.008 \pm 0.023 \pm 0.023$ measurement with uncertainties from statistics, systematic, and model. Note that this result is obtained for highly enriched ^{235}U reactor fuel while most other reactor experiments utilize a low-enrichment mix of fissile nuclides.

[2] ADEY 19 present a re-analysis of 1230 days of Daya Bay near detector data with reduced systematic uncertainties on the neutron detection efficiency. Note that ADEY 19 report the measured to predicted antineutrino ratio using the reactor model of MUELLER 11 (Huber-Mueller model). The ratio using the older ILL-Vogel model is $1.001 \pm 0.015 \pm 0.027$.

[3] AN 16 use 217 days of data (338k events) to determine the neutrino flux ratio relative to the prediction of Mueller-Huber and ILL-Vogel models (see AN 16 for details). The reported flux ratios were corrected for θ_{13} oscillation effect. The flux measurement is consistent with results from previous short-baseline reactor experiments. The measured inverse beta decay yield is $(1.55 \pm 0.04) \times 10^{-18}$ cm^2/(GW day) or $\sigma_f = (5.92 \pm 0.14) \times 10^{-43}$ cm^2/fission. About 4σ excess of events was observed in the 4–6 MeV prompt energy region.

[4] DENIZ 10 observe reactor $\overline{\nu}_e e$ scattering with recoil kinetic energies 3–8 MeV using CsI(Tl) detectors. The observed rate is consistent with the Standard Model prediction, leading to a constraint on $\sin^2\theta_W = 0.251 \pm 0.031(\text{stat}) \pm 0.024(\text{sys})$.

[5] Updated result of KamLAND, including the data used in EGUCHI 03. Note that the survival probabilities for different periods are not directly comparable because the effective baseline varies with power output of the reactor sources involved, and there were large variations in the reactor power production in Japan in 2003.

[6] EGUCHI 03 observe reactor neutrino disappearance at $\sim$ 180 km baseline to various Japanese nuclear power reactors.

[7] BOEHM 01 search for neutrino oscillations at 0.75 and 0.89 km distance from the Palo Verde reactors.

[8] APOLLONIO 99, APOLLONIO 98 search for neutrino oscillations at 1.1 km fixed distance from Chooz reactors. They use $\overline{\nu}_e p \rightarrow e^+ n$ in Gd-loaded scintillator target. APOLLONIO 99 supersedes APOLLONIO 98. See also APOLLONIO 03 for detailed description.

[9] GREENWOOD 96 search for neutrino oscillations at 18 m and 24 m from the reactor at Savannah River.

[10] DECLAIS 94 result based on integral measurement of neutrons only. Result is ratio of measured cross section to that expected in standard *V-A* theory. Replaced by ACHKAR 95.

[11] KWON 81 represents an analysis of a larger set of data from the same experiment as BOEHM 80.

Atmospheric neutrinos

Neutrinos and antineutrinos produced in the atmosphere induce μ-like and e-like events in underground detectors. The ratio of the numbers of the two kinds of events is defined as μ/e. It has the advantage that systematic effects, such as flux uncertainty, tend to cancel, for both experimental and theoretical values of the ratio. The "ratio of the ratios" of experimental to theoretical μ/e, $R(\mu/e)$, or that of experimental to theoretical μ/total, $R(\mu/\text{total})$ with total $= \mu + e$, is reported below. If the actual value is not unity, the value obtained in a given experiment may depend on the experimental conditions. In addition, the measured "up-down asymmetry" for μ ($N_{up}(\mu)/N_{down}(\mu)$) or e ($N_{up}(e)/N_{down}(e)$) is reported. The expected "up-down asymmetry" is nearly unity if there is no neutrino oscillation.

R(μ/e) = (Measured Ratio μ/e) / (Expected Ratio μ/e)

[1] ASHIE 05 results are based on an exposure of 92 kton yr during the complete Super-Kamiokande I running period. The analyzed data sample consists of fully-contained single-ring e-like events with 0.1 GeV/c $< p_e$ and μ-like events 0.2 GeV/c $< p_\mu$, both having a visible energy $<$ 1.33 GeV. These criteria match the definition used by FUKUDA 94.

[2] ASHIE 05 results are based on an exposure of 92 kton yr during the complete Super-Kamiokande I running period. The analyzed data sample consists of fully-contained single-ring events with visible energy $>$ 1.33 GeV and partially-contained events. All partially-contained events are classified as μ-like.

[3] SANCHEZ 03 result is based on an exposure of 5.9 kton yr, and updates ALLISON 99 result. The analyzed data sample consists of fully-contained e-flavor and μ-flavor events having lepton momentum $>$ 0.3 GeV/c.

[4] FUKUDA 96B studied neutron background in the atmospheric neutrino sample observed in the Kamiokande detector. No evidence for the background contamination was found.

[5] DAUM 95 results are based on an exposure of 2.0 kton yr which includes the data used by BERGER 90B. This ratio is for the contained and semicontained events. DAUM 95 also report $R(\mu/e) = 0.99 \pm 0.13 \pm 0.08$ for the total neutrino induced data sample which includes upward going stopping muons and horizontal muons in addition to the contained and semicontained events.

[6] FUKUDA 94 result is based on an exposure of 7.7 kton yr and updates the HIRATA 92 result. The analyzed data sample consists of fully-contained e-like events with 0.1 $< p_e <$ 1.33 GeV/c and fully-contained μ-like events with 0.2 $< p_\mu <$ 1.5 GeV/c.

[7] FUKUDA 94 analyzed the data sample consisting of fully contained events with visible energy $>$ 1.33 GeV and partially contained μ-like events.

[8] BECKER-SZENDY 92B reports the fraction of nonshowering events (mostly muons from atmospheric neutrinos) as $0.36 \pm 0.02 \pm 0.02$, as compared with expected fraction $0.51 \pm 0.01 \pm 0.05$. After cutting the energy range to the Kamiokande limits, BEIER 92 finds $R(\mu/e)$ very close to the Kamiokande value.

R(ν_μ) = (Measured Flux of ν_μ) / (Expected Flux of ν_μ)

[1] ADAMSON 06 uses a measurement of 107 total neutrinos compared to an expected rate of 127 $\pm$ 13 without oscillations.

[2] AMBROSIO 01 result is based on the upward through-going muon tracks with $E_\mu > 1$ GeV. The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration, is 6.17 years. The first error is the statistical error, the second is the systematic error, dominated by the theoretical error in the predicted flux.

[3] AMBROSIO 00 result is based on the upgoing partially contained event sample. It came from 4.1 live years of data taking with the full detector, from April 1994 to February 1999. The average energy of atmospheric muon neutrinos corresponding to this sample is 4 GeV. The first error is statistical, the second is the systematic error, dominated by the 25% theoretical error in the rate (20% in the flux and 15% in the cross section, added in quadrature). Within statistics, the observed deficit is uniform over the zenith angle.

[4] AMBROSIO 00 result is based on the combined samples of downgoing partially contained events and upgoing stopping events. These two subsamples could not be distinguished due to the lack of timing information. The result came from 4.1 live years of data taking with the full detector, from April 1994 to February 1999. The average energy of atmospheric muon neutrinos corresponding to this sample is 4 GeV. The first error is statistical, the second is the systematic error, dominated by the 25% theoretical error in the rate (20% in the flux and 15% in the cross section, added in quadrature). Within statistics, the observed deficit is uniform over the zenith angle.

[5] AMBROSIO 98 result is for all nadir angles and updates AHLEN 95 result. The lower cutoff on the muon energy is 1 GeV. In addition to the statistical and systematic errors, there is a Monte Carlo flux error (theoretical error) of $\pm$0.13. With a neutrino oscillation hypothesis, the fit either to the flux or zenith distribution independently yields $\sin^2 2\theta$=1.0 and $\Delta(m^2) \sim$ a few times 10^{-3} eV^2. However, the fit to the observed zenith distribution gives a maximum probability for χ^2 of only 5% for the best oscillation hypothesis.

[6] CASPER 91 correlates showering/nonshowering signature of single-ring events with parent atmospheric-neutrino flavor. They find nonshowering ($\approx \nu_\mu$ induced) fraction is $0.41 \pm 0.03 \pm 0.02$, as compared with expected 0.51 ± 0.05 (syst).

[7] AGLIETTA 89 finds no evidence for any anomaly in the neutrino flux. They define ρ = (measured number of ν_e's)/(measured number of ν_μ's). They report $\rho(\text{measured}) = \rho(\text{expected}) = 0.96^{+0.32}_{-0.28}$.

[8] From this data BOLIEV 81 obtain the limit $\Delta(m^2) \leq 6 \times 10^{-3}$ eV^2 for maximal mixing, $\nu_\mu \not\rightarrow \nu_\mu$ type oscillation.

$0.96^{+0.38}_{-0.27}\pm0.15$	[6] ADAMSON	06	MINS	atmospheric ν with far detector

[1] ADAMSON 12B reports the atmospheric neutrino results obtained with MINOS far detector in 2,553 live days (an exposure of 37.9 kton-yr). The muon charge ratio N(μ^+)/N(μ^-) represents the $\overline{\nu}_\mu/\nu_\mu$ ratio. As far as the same oscillation parameters are used for νs and $\overline{\nu}$s, the expected $\overline{\nu}_\mu/\nu_\mu$ ratio is almost entirely independent of any input oscillations.

[2] This result is obtained with a charge-separated sample of high resolution contained-vertex muons.

[3] This result is obtained with a charge-separated sample of high resolution neutrino-induced rock-muons.

[4] The charge-separated samples of high resolution contained-vertex muons and neutrino-induced rock-muons are combined to obtain this result which is consistent with unity.

[5] ADAMSON 07 result is obtained with the MINOS far detector in 854.24 live days, based on neutrino-induced upward-going and horizontal muons. This result is consistent with CPT conservation.

[6] ADAMSON 06 result is obtained with the MINOS far detector with an exposure of 4.54 kton yr, based on contained events. The expected ratio is calculated by assuming the same oscillation parameters for neutrinos and antineutrinos.

Solar neutrinos

Solar neutrinos are produced by thermonuclear fusion reactions in the Sun. Radiochemical experiments measure particular combinations of fluxes from various neutrino-producing reactions, whereas water-Cherenkov experiments mainly measure a flux of neutrinos from decay of ^{8}B. Solar neutrino fluxes are composed of all active neutrino species, ν_e, ν_μ, and ν_τ. In addition, some other mechanisms may cause antineutrino components in solar neutrino fluxes. Each measurement method is sensitive to a particular component or a combination of components of solar neutrino fluxes.

ν_e Capture Rates from Radiochemical Experiments

1 SNU (Solar Neutrino Unit) = 10^{-36} captures per atom per second.

VALUE (SNU)	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
$73.4\ ^{+6.1}_{-6.0}\ ^{+3.7}_{-4.1}$	[1] KAETHER	10		GALX reanalysis
$67.6\pm4.0\pm3.2$	[2] KAETHER	10		GNO+GALX reanalysis combined
$65.4\ ^{+3.1}_{-3.0}\ ^{+2.6}_{-2.8}$	[3] ABDURASHI...	09	SAGE	^{71}Ga $\rightarrow$ ^{71}Ge
$62.9\ ^{+5.5}_{-5.3}\pm2.5$	[4] ALTMANN	05	GNO	^{71}Ga $\rightarrow$ ^{71}Ge
$69.3\pm4.1\pm3.6$	[5] ALTMANN	05	GNO	GNO + GALX combined
$77.5\pm6.2\ ^{+4.3}_{-4.7}$	[6] HAMPEL	99	GALX	^{71}Ga $\rightarrow$ ^{71}Ge
$2.56\pm0.16\pm0.16$	[7] CLEVELAND	98	HOME	^{37}Cl $\rightarrow$ ^{37}Ar

[1] KAETHER 10 reports the reanalysis results of a complete GALLEX data (GALLEX I+II+III+IV, reported in HAMPEL 99) based on the event selection with a new pulse shape analysis, which provides a better background reduction than the rise time analysis adopted in HAMPEL 99.

[2] Combined result of GALLEX I+II+III+IV reanalysis and GNO I+II+III (ALTMANN 05).

[3] ABDURASHITOV 09 reports a combined analysis of 168 extractions of the SAGE solar neutrino experiment during the period January 1990 through December 2007, and updates the ABDURASHITOV 02 result. The data are consistent with the assumption that the solar neutrino production rate is constant in time. Note that a $\sim$ 15% systematic uncertainty in the overall normalization may be added to the ABDURASHITOV 09 result, because calibration experiments for gallium solar neutrino measurements using intense ^{51}Cr (twice by GALLEX and once by SAGE) and ^{37}Ar (by SAGE) result in an average ratio of 0.87 $\pm$ 0.05 of the observed to calculated rates.

[4] ALTMANN 05 reports the complete result from the GNO solar neutrino experiment (GNO I+II+III), which is the successor project of GALLEX. Experimental technique of GNO is essentially the same as that of GALLEX. The run data cover the period 20 May 1998 through 9 April 2003.

[5] Combined result of GALLEX I+II+III+IV (HAMPEL 99) and GNO I+II+III.

[6] HAMPEL 99 report the combined result for GALLEX I+II+III+IV (65 runs in total), which update the HAMPEL 96 result. The GALLEX IV result (12 runs) is 118.4 $\pm$ 17.8 $\pm$ 6.6 SNU. (HAMPEL 99 discuss the consistency of partial results with the mean.) The GALLEX experimental program has been completed with these runs. The total run data cover the period 14 May 1991 through 23 January 1997. A total of 300 ^{71}Ge events were observed. Note that a $\sim$ 15% systematic uncertainty in the overall normalization may be added to the HAMPEL 99 result, because calibration experiments for gallium solar neutrino measurements using intense ^{51}Cr (twice by GALLEX and once by SAGE) and ^{37}Ar (by SAGE) result in an average ratio of 0.87$\pm$0.05 of the observed to calculated rates.

[7] CLEVELAND 98 is a detailed report of the ^{37}Cl experiment at the Homestake Mine. The average solar neutrino-induced ^{37}Ar production rate from 108 runs between 1970 and 1994 updates the DAVIS 89 result.

ϕ_{ES} (^{8}B)

^{8}B solar-neutrino flux measured via νe elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to ν_μ, ν_τ due to the cross-section difference, $\sigma(\nu_{\mu,\tau}e) \sim 0.16\sigma(\nu_e e)$. If the ^{8}B solar-neutrino flux involves nonelectron flavor active neutrinos, their contribution to the flux is $\sim$ 0.16 times of ν_e.

[1] AGOSTINI 20A obtained this result from the $\nu_e e$ elastic scattering rate over the period between January 2008 and December 2016. Uses the same data as AGOSTINI 18B, but the analysis technique is significantly improved.

[2] ANDERSON 19 reports this result from the $\nu_e e$ elastic scattering rate using a 69.2 kton-day (or 114.7 days) of exposure from May through December, 2017 during the SNO+ detector's water commissioning phase. The events over the reconstructed electron kinetic energy range of 5–15 MeV were analyzed.

[3] AGOSTINI 18B obtained this result from the $\nu_e e$ elastic scattering rate over the period between January 2008 and December 2016.

[4] ABE 16C reports the combined results of the four phases of the Super-Kamiokande average flux measurements. Here the revised Super-Kamiokande-III result is used.

[5] ABE 16C reports the Super-Kamiokande-IV results for 1664 live days from September 2008 to February 2014. The analysis threshold is total electron energy of 4.0 MeV.

[6] ABE 16C revised the Super-Kamiokande-III average flux value reported in ABE 11. Super-Kamiokande-III results are for 548 live days from August 4, 2006 to August 18, 2008. The analysis threshold is 5.0 MeV, but the event sample in the 5.0–6.5 MeV total electron energy range has a total live time of 298 days.

[7] ABE 11 recalculated the Super-Kamiokande-II results using ^{8}B spectrum of WINTER 06A.

[8] ABE 11 recalculated the Super-Kamiokande-I results using ^{8}B spectrum of WINTER 06A.

[9] ABE 11B use a 123 kton-day exposure of the KamLAND liquid scintillation detector to measure the ^{8}B solar neutrino flux. They utilize $\nu - e$ elastic scattering above a reconstructed-energy threshold of 5.5 MeV, corresponding to 5 MeV electron recoil energy. 299 electron recoil candidate events are reported, of which 157 ± 23.6 are assigned to background.

[10] BELLINI 10A reports the Borexino result with 3 MeV energy threshold for scattered electrons. The data correspond to 345.3 live days with a target mass of 100 t, between July 15, 2007 and August 23, 2009.

[11] AHARMIM 08 reports the results from SNO Phase III measurement using an array of ^{3}He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17 live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the ^{8}B shape.

[12] CRAVENS 08 reports the Super-Kamiokande-II results for 791 live days from December 2002 to October 2005. The photocathode coverage of the detector is 19% (reduced from 40% of that of Super-Kamiokande-I due to an accident in 2001). The analysis threshold for the average flux is 7 MeV.

[13] HOSAKA 06 reports the final results for 1496 live days with Super-Kamiokande-I between May 31, 1996 and July 15, 2001, and replace FUKUDA 02 results. The analysis threshold is 5 MeV except for the first 280 live days (6.5 MeV).

[14] AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04A. The *CC*, *ES*, and *NC* events were statistically separated. In one method, the ^{8}B energy spectrum was not constrained. In the other method, the constraint of an undistorted ^{8}B energy spectrum was added for comparison with AHMAD 02 results.

[15] AHMAD 02 reports the ^{8}B solar-neutrino flux measured via νe elastic scattering above the kinetic energy threshold of 5 MeV. The data correspond to 306.4 live days with SNO between November 2, 1999 and May 28, 2001, and updates AHMAD 01 results.

[16] AHMAD 01 reports the ^{8}B solar-neutrino flux measured via νe elastic scattering above the kinetic energy threshold of 6.75 MeV. The data correspond to 241 live days with SNO between November 2, 1999 and January 15, 2001.

[17] FUKUDA 96 results are for a total of 2079 live days with Kamiokande II and III from January 1987 through February 1995, covering the entire solar cycle 22, with threshold $E_e > 9.3$ MeV (first 449 days), > 7.5 MeV (middle 794 days), and > 7.0 MeV (last 836 days). These results update the HIRATA 90 result for the average ^{8}B solar-neutrino flux and HIRATA 91 result for the day-night variation in the ^{8}B solar-neutrino flux. The total data sample was also analyzed for short-term variations: within experimental errors, no strong correlation of the solar-neutrino flux with the sunspot numbers was found.

ϕ_{CC} (^{8}B)

^{8}B solar-neutrino flux measured with charged-current reaction which is sensitive exclusively to ν_e.

[1] AHARMIM 08 reports the results from SNO Phase III measurement using an array of ^{3}He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17 live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the ^{8}B shape.

[2] AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04A. The *CC*, *ES*, and *NC* events were statistically separated. In one method, the ^{8}B energy spectrum was not constrained. In the other method, the constraint of an undistorted ^{8}B energy spectrum was added for comparison with AHMAD 02 results.

[3] AHMAD 02 reports the SNO result of the ^{8}B solar-neutrino flux measured with charged-current reaction on deuterium, $\nu_e d \rightarrow pp e^-$, above the kinetic energy threshold of 5 MeV. The data correspond to 306.4 live days with SNO between November 2, 1999 and May 28, 2001, and updates AHMAD 01 results. The complete description of the SNO Phase I data set is given in AHARMIM 07.

[4] AHMAD 01 reports the first SNO result of the ^{8}B solar-neutrino flux measured with the charged-current reaction on deuterium, $\nu_e d \rightarrow pp e^-$, above the kinetic energy threshold of 6.75 MeV. The data correspond to 241 live days with SNO between November 2, 1999 and January 15, 2001.

ϕ_{NC} (^{8}B)

^{8}B solar neutrino flux measured with neutral-current reaction, which is equally sensitive to ν_e, ν_μ, and ν_τ.

[1] MA 23A searched for ^{8}B solar neutrinos elastically scattered off xenon nuclei in the commissioning phase of the PANDAX-4T experiment with an effective exposure of 0.48 ton-yr. This experiment is dedicated to dark matter direct search using a dual-phase xenon TPC with a sensitive volume of 3.7 tons of liquid Xe.

[2] AHARMIM 13 obtained this result from a combined analysis of the data from all three phases, SNO-I, II, and III. The measurement of the ^{8}B flux mostly comes from the NC signal, however, CC contribution is included in the fit.

[3] AHARMIM 10 reports this result from a joint analysis of SNO Phase I+II data with the "effective electron kinetic energy" threshold of 3.5 MeV. This result is obtained with a "binned-histogram unconstrained fit" where binned probability distribution functions of the neutrino signal observables were used without any model constraints on the shape of the neutrino spectrum.

[4] AHARMIM 08 reports the results from SNO Phase III measurement using an array of ^{3}He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17 live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the ^{8}B shape.

[5] AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04A. The *CC*, *ES*, and *NC* events were statistically separated. In one method, the ^{8}B energy spectrum was not constrained. In the other method, the constraint of an undistorted ^{8}B energy spectrum was added for comparison with AHMAD 02 results.

[6] AHMAD 02 reports the first SNO result of the ^{8}B solar-neutrino flux measured with the neutral-current reaction on deuterium, $\nu_\ell d \rightarrow np\nu_\ell$, above the neutral-current reaction threshold of 2.2 MeV. The data correspond to 306.4 live days with SNO between November 2, 1999 and May 28, 2001. The complete description of the SNO Phase I data set is given in AHARMIM 07.

$\phi_{\nu_\mu+\nu_\tau}$ (^{8}B)

5.44 ± 0.99	[8] AHMAD	01		Derived from SNO+SuperKam, water Cherenkov

[1] ANDERSON 19 reports this result from the measured $\nu_e e$ elastic scattering rate using a 69.2 kton·day (or 114.7 days) of exposure from May through December, 2017 during the SNO+ detector's water commissioning phase, assuming the neutrino mixing parameters given in PDG 16 and a standard solar model given in BAHCALL 05.

[2] AGOSTINI 18B obtained this result from the measured $\nu_e e$ elastic scattering rate over the period between January 2008 and December 2016, assuming the MSW-LMA oscillation parameters derived by ESTEBAN 17. Assuming a high-metalicity standard solar model, the electron neutrino survival probability for the ^{8}B solar neutrino is calculated to be 0.37 ± 0.08.

[3] AHARMIM 13 obtained this result from a combined analysis of the data from all three phases, SNO-I, II, and III. The measurement of the ^{8}B flux mostly comes from the NC signal, however, CC contribution is included in the fit.

[4] AHARMIM 10 reports this result from a joint analysis of SNO Phase I+II data with the "effective electron kinetic energy" threshold of 3.5 MeV. This result is obtained with the assumption of unitarity, which relates the NC, CC, and ES rates. The data were fit with the free parameters directly describing the total ^{8}B neutrino flux and the energy-dependent ν_e survival probability.

[5] AHARMIM 08 reports the results from SNO Phase III measurement using an array of ^{3}He proportional counters to measure the rate of NC interactions in heavy water, over the period between November 27, 2004 and November 28, 2006, corresponding to 385.17 live days. A simultaneous fit was made for the number of NC events detected by the proportional counters and the numbers of NC, CC, and ES events detected by the PMTs, where the spectral distributions of the ES and CC events were not constrained to the ^{8}B shape.

[6] AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, corresponding to 391.4 live days, and update AHMED 04A. The CC, ES, and NC events were statistically separated. In one method, the ^{8}B energy spectrum was not constrained. In the other method, the constraint of an undistorted ^{8}B energy spectrum was added for comparison with AHMAD 02 results.

[7] AHMAD 02 determined the total flux of active ^{8}B solar neutrinos by directly measuring the neutral-current reaction, $\nu_\ell d \rightarrow np\nu_\ell$, which is equally sensitive to ν_e, ν_μ, and ν_τ. The complete description of the SNO Phase I data set is given in AHARMIM 07.

[8] AHMAD 01 deduced the total flux of active ^{8}B solar neutrinos by combining the SNO charged-current result (AHMAD 01) and the Super-Kamiokande νe elastic-scattering result (FUKUDA 01).

Total Flux of Active CNO Solar Neutrinos

Total flux of active neutrinos (ν_e,ν_μ,ν_τ).

VALUE (10^8 cm^{-2} s^{-1})	CL%	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •					
$6.7 ^{+1.2}_{-0.8}$		[1] BASILICO	23	BORX	$\nu_e e$ directional + spectral information
$6.6 ^{+2.0}_{-0.9}$		[2] APPEL	22	BORX	$\nu_e e$ scattering rate
$7.0 ^{+3.0}_{-2.0}$		[3] AGOSTINI	20D	BORX	$\nu_e e$ scattering rate
<7.9	95	[4] AGOSTINI	18B	BORX	$\nu_e e$ scattering rate

[1] BASILICO 23 obtained this result by combining the newly developed Correlated Integrated Directionality (CID)-based CNO result obtained by using the complete Borexino data-taking period from 2007 to 2021, with a spectral fit of the Phase-III dataset (from July 2016 to October 2021, characterized by a thermally stable detector). Note that the directional information is independent from the spectral information on which the previous CNO solar neutrino measurements by Borexino were based. Neutrino flavor conversion was taken into account.

[2] APPEL 22 obtained this result from the measured $\nu_e e$ elastic scattering rate over the period between January 2017 and October 2021, assuming the MSW-LMA oscillation parameters derived by ESTEBAN 20A. The exposure corresponding to this data is 1431.6 days × 71.3 tons.

[3] AGOSTINI 20D obtained this result from the measured $\nu_e e$ elastic scattering rate over the period between July 2016 to February 2020, assuming the MSW-LMA oscillation parameters derived by CAPOZZI 18.

[4] AGOSTINI 18B obtained this result from an upper limit of the $\nu_e e$ elastic scattering rate for the CNO neutrinos over the period between December 2011 and May 2016, assuming the MSW-LMA oscillation parameters derived by ESTEBAN 17.

Total Flux of Active hep Solar Neutrinos

Total flux of active neutrinos (ν_e,ν_μ,ν_τ).

• • • We do not use the following data for averages, fits, limits, etc. • • •					
<1.8	90	[1] AGOSTINI	20A	BORX	$\nu_e e$ scattering and ^{12}C$(\nu,\nu')^{12}$C*
<0.3	90	[2] AHARMIM	20	SNO	CC, NC, $\nu_e e$ scattering
<2.2	90	[3] AGOSTINI	18B	BORX	$\nu_e e$ scattering rate

[1] AGOSTINI 20A obtained this result from an upper limit of the $\nu_e e$ elastic scattering rate and NC-mediated inelastic scattering on carbon nuclei with 15.1 MeV deexcitation γ-ray for the hep neutrino. The dataset corresponds to an effective exposure of 0.745 kt·yr from November 2009 to October 2017. A FADC DAQ system, optimized for the acquisition of high-energy events was used for data collection. The MSW-LMA oscillation parameters derived by ESTEBAN 17 were assumed.

[2] AHARMIM 20 uses the entire SNO dataset, corresponding to 2.47 kton·yrs of exposure after fiducialization. With the D_2O target, SNO was sensitive to charged current, neutral current, and elastic scattering channels.

[3] AGOSTINI 18B obtained this result from an upper limit of the $\nu_e e$ elastic scattering rate for the hep neutrino using the dataset corresponding to an exposure of 0.8 kt·yr and assuming the MSW-LMA oscillation parameters derived by ESTEBAN 17.

$0.07 \pm 0.049^{+0.013}_{-0.012}$	[9] AHMAD	02B	SNO	Const. of no ϕ_{NC} asymmetry

[1] ABE 16C reports the combined day-night flux asymmetry results of the four phases of the Super-Kamiokande measurements. Amplitude fit method is used. See footnote to RENSHAW 14.

[2] ABE 16C reports the Super-Kamiokande-IV results for 1664 live days from September 2008 to February 2014. The analysis threshold for day-night flux asymmetry is recoil electron energy of 4.49 MeV (total electron energy of 5.0 MeV). Amplitude fit method is used. See footnote to RENSHAW 14.

[3] RENSHAW 14 obtains this result by using the "amplitude fit" introduced in SMY 04. The data from the Super-Kamiokande(SK)-I, -II, -III, and 1306 live days of the SK-IV measurements are used. The analysis threshold is recoil-electron kinetic energy of 4.5 MeV for SK-III, and SK-IV except for 250 live days in SK-III (6.0 MeV). The analysis threshold for SK-I and SK-II is the same as in the previous reports. (Note that in the previous SK solar-neutrino results, the analysis threshold is quoted as recoil-electron total energy.) This day-night asymmetry result is consistent with neutrino oscillations for 4×10^{-5} eV^2 $< \Delta m^2_{21} < 7 \times 10^{-5}$ eV^2 and large mixing values of θ_{12} at the 68% CL.

[4] CRAVENS 08 reports the Super-Kamiokande-II results for 791 live days from December 2002 to October 2005. The photocathode coverage of the detector is 19% (reduced from 40% of that of Super-Kamiokande-I due to an accident in 2001). The analysis threshold for the day and night fluxes is 7.5 MeV except for the first 159 live days (8.0 MeV).

[5] HOSAKA 06 reports the final results for 1496 live days with Super-Kamiokande-I between May 31, 1996 and July 15, 2001, and replace FUKUDA 02 results. The analysis threshold is 5 MeV except for the first 280 live days (6.5 MeV).

[6] This result with reduced statistical uncertainty is obtained by assuming two-neutrino oscillations within the LMA (large mixing angle) region and by fitting the time variation of the solar neutrino flux measured via ν_e elastic scattering to the variations expected from neutrino oscillations. For details, see SMY 04. There is an additional small systematic error of ± 0.0004 coming from uncertainty of oscillation parameters.

[7] AHARMIM 05A measurements were made with dissolved NaCl (0.195% by weight) in heavy water over the period between July 26, 2001 and August 28, 2003, with 176.5 days of the live time recorded during the day and 214.9 days during the night. This result is obtained with the spectral distribution of the CC events not constrained to the ^{8}B shape.

[8] AHMAD 02B results are based on the charged-current interactions recorded between November 2, 1999 and May 28, 2001, with the day and night live times of 128.5 and 177.9 days, respectively. The complete description of the SNO Phase I data set is given in AHARMIM 07.

[9] AHMAD 02B results are derived from the charged-current interactions, neutral-current interactions, and νe elastic scattering, with the total flux of active neutrinos constrained to have no asymmetry. The data were recorded between November 2, 1999 and May 28, 2001, with the day and night live times of 128.5 and 177.9 days, respectively. The complete description of the SNO Phase I data set is given in AHARMIM 07.

ϕ_{ES} (^{7}Be)

^{7}Be solar-neutrino flux measured via ν_e elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to ν_μ, ν_τ due to the cross-section difference, $\sigma(\nu_{\mu,\tau}\, e) \sim 0.2\, \sigma(\nu_e\, e)$. If the ^{7}Be solar-neutrino flux involves nonelectron flavor active neutrinos, their contribution to the flux is ~ 0.2 times that of ν_e.

3.38 ± 0.47	[1] ABDURASHI...	09	FIT	Fit existing solar-ν data

[1] ABDURASHITOV 09 reports the pp solar-neutrino flux derived from the Ga solar neutrino capture rate by subtracting contributions from ^{8}B, ^{7}Be, pep and CNO solar neutrino fluxes determined by other solar neutrino experiments as well as neutrino oscillation parameters determined from available world neutrino oscillation data.

ϕ_{ES} (hep)

hep solar-neutrino flux measured via νe elastic scattering. This process is sensitive to all active neutrino flavors, but with reduced sensitivity to ν_μ, ν_τ due to the cross-section difference, $\sigma(\nu_{\mu,\tau}\, e) \sim 0.16 \sigma(\nu_e e)$. If the hep solar-neutrino flux involves nonelectron flavor active neutrinos, their contribution to the flux is ~ 0.16 times of ν_e.

• • • We do not use the following data for averages, fits, limits, etc. • • •				
<73	90	[1] HOSAKA	06	SKAM

[1] HOSAKA 06 result is obtained from the recoil electron energy window of 18–21 MeV, and updates FUKUDA 01 result.

$\phi_{\overline{\nu}_e}$ (^{8}B)

Searches are made for electron antineutrino flux from the Sun. Flux limits listed here are derived relative to the BS05(OP) Standard Solar Model ^{8}B solar neutrino flux (5.69×10^6 cm^{-2}s^{-1}), with an assumption that solar $\overline{\nu}_e$s follow an unoscillated ^{8}B neutrino spectrum.

<0.7	90	GANDO	03	SKAM	$8.0 < E_{\overline{\nu}_e} < 20.0$ MeV
<1.7	90	AGLIETTA	96	LSD	$7 < E_{\overline{\nu}_e} < 17$ MeV

[1] AGOSTINI 21 derived this result relative to the Standard Solar Model ^{8}B solar neutrino flux, under an assumption of high solar metallicity, of $5.46\ (1 \pm 0.12) \times 10^6$ cm^{-2}s^{-1} (see VINYOLES 17).

[2] Superseded by AGOSTINI 21.

[3] BALATA 06 obtained this result from the search for $\overline{\nu}_e$ interactions with Counting Test Facility (the prototype of the Borexino detector).

(B) Three-neutrino mixing parameters

$\sin^2(\theta_{12})$

If an experiment reports $\sin^2(2\theta_{12})$ we convert the value to $\sin^2(\theta_{12})$.

[1] ABE 16C obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, using all solar data and KamLAND data. *CPT* invariance is assumed.

[2] SALAS 21 reports results of a global fit to neutrino oscillation data available at the time of the Neutrino 2020 conference.

[3] ESTEBAN 20A reports results of a global fit to neutrino oscillation data available at the time of the Neutrino2020 conference.

[4] ABE 16C obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, using Super-Kamiokande (I+II+III+IV) and SNO data.

[5] ABE 16C obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, by combining the four phases of the Super-Kamiokande solar data.

[6] ABE 16C obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, using the Super-Kamiokande-IV data.

[7] FORERO 14 performs a global fit to neutrino oscillations using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.

[8] GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as $0.304^{+0.013}_{-0.012}$ for normal and $0.305^{+0.012}_{-0.013}$ for inverted mass ordering.

[9] AHARMIM 13 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.

[10] AHARMIM 13 global solar neutrino data include SNO's all-phases-combined analysis results on the total active ^{8}B neutrino flux and energy-dependent ν_e survival probability parameters, measurements of Cl (CLEVELAND 98), Ga (ABDURASHITOV 09 which contains combined analysis with GNO (ALTMANN 05 and Ph.D. thesis of F. Kaether)), and ^{7}Be (BELLINI 11A) rates, and ^{8}B solar-neutrino recoil electron measurements of SK-I (HOSAKA 06) zenith, SK-II (CRAVENS 08) and SK-III (ABE 11) day/night spectra, and Borexino (BELLINI 10A) spectra.

[11] AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{32} fixed to 2.45×10^{-3} eV^2, using global solar neutrino data.

[12] AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{32} fixed to 2.45×10^{-3} eV^2, using global solar neutrino and KamLAND (GANDO 11) data. CPT invariance is assumed.

[13] GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND, global solar neutrino, short-baseline (SBL) reactor, and accelerator data, assuming *CPT* invariance. Supersedes GANDO 11.

[14] GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND and global solar neutrino data, assuming CPT invariance. Supersedes GANDO 11.

[15] GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND data. Supersedes GANDO 11.

[16] ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. CPT invariance is assumed.

[17] ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, and SAGE data.

[18] ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{32} fixed to 2.4×10^{-3} eV^2, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. The normal neutrino mass ordering and CPT invariance are assumed.

[19] ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{32} fixed to 2.4×10^{-3} eV^2, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, and GALLEX/GNO data. The normal neutrino mass ordering is assumed.

[20] BELLINI 11A obtained this result by a two-neutrino oscillation analysis using KamLAND, Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the ^{8}B flux was left free. CPT invariance is assumed.

[21] BELLINI 11A obtained this result by a two-neutrino oscillation analysis using Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the ^{8}B flux was left free.

[22] GANDO 11 obtain this result with three-neutrino fit using the KamLAND + solar data. Superseded by GANDO 13.

[23] GANDO 11 obtain this result with three-neutrino fit using the KamLAND data only. Superseded by GANDO 13.

[24] AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), Cl (CLEVELAND 98), SAGE (ABDURASHITOV 09), Gallex/GNO (HAMPEL 99, ALTMANN 05), Borexino (ARPESELLA 08A), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).

[25] AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data and KamLAND data (ABE 08A). *CPT* invariance is assumed.

[26] AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.

[27] AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{31} fixed to 2.3×10^{-3} eV^2, using global solar neutrino data and KamLAND data (ABE 08A). *CPT* invariance is assumed.

[28] AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{31} fixed to 2.3×10^{-3} eV^2, using global solar neutrino data.

[29] ABE 08A obtained this result by a rate + shape + time combined geoneutrino and reactor two-neutrino fit for Δm^2_{21} and $\tan^2\theta_{12}$, using KamLAND data only. Superseded by GANDO 11.

[30] ABE 08A obtained this result by means of a two-neutrino fit using KamLAND, Homestake, SAGE, GALLEX, GNO, SK (zenith angle and E-spectrum), the SNO χ^2-map, and solar flux data. *CPT* invariance is assumed. Superseded by GANDO 11.

[31] The result given by AHARMIM 08 is $\theta = (34.4^{+1.3}_{-1.2})^\circ$. This result is obtained by a two-neutrino oscillation analysis using solar neutrino data including those of Borexino (ARPESELLA 08A) and Super-Kamiokande-I (HOSAKA 06), and KamLAND data (ABE 08A). *CPT* invariance is assumed.

[32] HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using SK ν_e data, CC data from other solar neutrino experiments, and KamLAND data (ARAKI 05). *CPT* invariance is assumed.

[33] HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the data from Super-Kamiokande, SNO (AHMAD 02 and AHMAD 02B), and KamLAND (ARAKI 05) experiments. *CPT* invariance is assumed.

[34] HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02B) solar neutrino data.

[35] The result given by AHARMIM 05A is $\theta = (33.9 \pm 1.6)^\circ$. This result is obtained by a two-neutrino oscillation analysis using SNO pure deuteron and salt phase data, SK ν_e data, Cl and Ga CC data, and KamLAND data (ARAKI 05). *CPT* invariance is assumed. AHARMIM 05A also quotes $\theta = (33.9^{+2.4}_{-2.2})^\circ$ as the error enveloping the 68% CL two-dimensional region. This translates into $\sin^2 2\theta = 0.86^{+0.05}_{-0.06}$.

[36] AHARMIM 05A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in figure 35a of AHARMIM 05A. AHARMIM 05A also quotes $\tan^2\theta = 0.45^{+0.09}_{-0.08}$ as the error enveloping the 68% CL two-dimensional region. This translates into $\sin^2 2\theta = 0.86^{+0.05}_{-0.07}$.

[37] ARAKI 05 obtained this result by a two-neutrino oscillation analysis using KamLAND and solar neutrino data. *CPT* invariance is assumed. The 1σ error shown here is translated from the number provided by the KamLAND collaboration, $\tan^2\theta = 0.40^{+0.07}_{-0.05}$. The corresponding number quoted in ARAKI 05 is $\tan^2\theta = 0.40^{+0.10}_{-0.07}$ ($\sin^2 2\theta = 0.82 \pm 0.07$), which envelops the 68% CL two-dimensional region.

[38] The result given by AHMED 04A is $\theta = (32.5^{+1.7}_{-1.6})^\circ$. This result is obtained by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (EGUCHI 03). *CPT* invariance is assumed. AHMED 04A also quotes $\theta = (32.5^{+2.4}_{-2.3})^\circ$ as the error enveloping the 68% CL two-dimensional region. This translates into $\sin^2 2\theta = 0.82 \pm 0.06$.

[39] AHMED 04A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 5(a) of AHMED 04A. The best-fit point is $\Delta(m^2) = 6.5 \times 10^{-5}$ eV^2, $\tan^2\theta = 0.40$ ($\sin^2 2\theta = 0.82$).

[40] The result given by SMY 04 is $\tan^2\theta = 0.44 \pm 0.08$. This result is obtained by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (IANNI 03). *CPT* invariance is assumed.

[41] SMY 04 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The 1σ errors are read from Fig. 6(a) of SMY 04.

[42] SMY 04 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02B) solar neutrino data. The 1σ errors are read from Fig. 6(a) of SMY 04.

[43] AHMAD 02B obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4(b) of AHMAD 02B. The best fit point is $\Delta(m^2) = 5.0 \times 10^{-5}$ eV^2 and $\tan\theta = 0.34$ ($\sin^2 2\theta = 0.76$).

[44] FUKUDA 02 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4 of FUKUDA 02. The best fit point is $\Delta(m^2) = 6.9 \times 10^{-5}$ eV^2 and $\tan^2\theta = 0.38$ ($\sin^2 2\theta = 0.80$).

[1] GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND, global solar neutrino, short-baseline (SBL) reactor, and accelerator data, assuming CPT invariance. Supersedes GANDO 11.

[2] SALAS 21 reports results of a global fit to neutrino oscillation data available at the time of the Neutrino 2020 conference.

[3] ESTEBAN 20A reports results of a global fit to neutrino oscillation data available at the time of the Neutrino2020 conference.

[4] ABE 16C obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, using all solar data and KamLAND data. *CPT* invariance is assumed.

[5] ABE 16C obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, using Super-Kamiokande (I+II+III+IV) and SNO data.

[6] ABE 16C obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, by combining the four phases of the Super-Kamiokande solar data.

[7] ABE 16C obtained this result by a three-neutrino oscillation analysis, with a constraint of $\sin^2(\theta_{13}) = 0.0219 \pm 0.0014$ coming from reactor neutrino experiments, using the Super-Kamiokande-IV data.

[8] FORERO 14 performs a global fit to Δm^2_{21} using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.

[9] GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as $(7.50^{+0.19}_{-0.17}) \times 10^{-5}$ eV^2 for normal and $(7.50^{+0.18}_{-0.17}) \times 10^{-5}$ eV^2 for inverted mass ordering.

[10] AHARMIM 13 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.

[11] AHARMIM 13 global solar neutrino data include SNO's all-phases-combined analysis results on the total active ^{8}B neutrino flux and energy-dependent ν_e survival probability parameters, measurements of Cl (CLEVELAND 98), Ga (ABDURASHITOV 09 which contains combined analysis with GNO (ALTMANN 05 and Ph.D. thesis of F. Kaether)), and ^{7}Be (BELLINI 11A) rates, and ^{8}B solar-neutrino recoil electron measurements of SK-I (HOSAKA 06) zenith, SK-II (CRAVENS 08), and SK-III (ABE 11) day/night spectra, and Borexino (BELLINI 10A) spectra.

[12] AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{31} fixed to 2.45×10^{-3} eV^2, using global solar neutrino data.

[13] AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{31} fixed to 2.45×10^{-3} eV^2, using global solar neutrino and KamLAND data (GANDO 11). CPT invariance is assumed.

[14] GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND and global solar neutrino data, assuming CPT invariance. Supersedes GANDO 11.

[15] GANDO 13 obtained this result by a three-neutrino oscillation analysis using KamLAND data. Supersedes GANDO 11.

[16] ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. CPT invariance is assumed.

[17] ABE 11 obtained this result by a two-neutrino oscillation analysis using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, and SAGE data.

[18] ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{32} fixed to 2.4×10^{-3} eV^2, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. The normal neutrino mass ordering and CPT invariance are assumed.

[19] ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{32} fixed to 2.4×10^{-3} eV^2, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, and GALLEX/GNO data. The normal neutrino mass ordering is assumed.

[20] BELLINI 11A obtained this result by a two-neutrino oscillation analysis using KamLAND, Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the ^{8}B flux was left free. CPT invariance is assumed.

[21] BELLINI 11A obtained this result by a two-neutrino oscillation analysis using Homestake, SAGE, Gallex, GNO, Kamiokande, Super-Kamiokande, SNO, and Borexino (BELLINI 11A) data and the SSM flux prediction in SERENELLI 11 (Astrophysical Journal **743** 24 (2011)) with the exception that the ^{8}B flux was left free.

[22] GANDO 11 obtain this result with three-neutrino fit using the KamLAND + solar data. Superseded by GANDO 13.

[23] GANDO 11 obtain this result with three-neutrino fit using the KamLAND data only. Supersedes ABE 08A.

[24] AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), Cl (CLEVELAND 98), SAGE (ABDURASHITOV 09), Gallex/GNO (HAMPEL 99, ALTMANN 05), Borexino (ARPESELLA 08A), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).

[25] AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data and KamLAND data (ABE 08A). *CPT* invariance is assumed.

[26] AHARMIM 10 obtained this result by a two-neutrino oscillation analysis using global solar neutrino data.

[27] AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{31} fixed to 2.3×10^{-3} eV^2, using global solar neutrino data and KamLAND data (ABE 08A). *CPT* invariance is assumed.

[28] AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{31} fixed to 2.3×10^{-3} eV^2, using global solar neutrino data.

[29] ABE 08A obtained this result by a rate + shape + time combined geoneutrino and reactor two-neutrino fit for Δm^2_{21} and $\tan^2\theta_{12}$, using KamLAND data only. Superseded by GANDO 11.

[30] ABE 08A obtained this result by means of a two-neutrino fit using KamLAND, Homestake, SAGE, GALLEX, GNO, SK (zenith angle and E-spectrum), the SNO χ^2-map, and solar flux data. *CPT* invariance is assumed. Superseded by GANDO 11.

[31] AHARMIM 08 obtained this result by a two-neutrino oscillation analysis using all solar neutrino data including those of Borexino (ARPESELLA 08A) and Super-Kamiokande-I (HOSAKA 06), and KamLAND data (ABE 08A). *CPT* invariance is assumed.

[32] HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (ARAKI 05). *CPT* invariance is assumed.

[33] HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the data from Super-Kamiokande, SNO (AHMAD 02 and AHMAD 02B), and KamLAND (ARAKI 05) experiments. *CPT* invariance is assumed.

[34] HOSAKA 06 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02B) solar neutrino data.

[35] HOSAKA 06 obtained this result from the consistency between the observed and expected day-night flux asymmetry amplitude. The listed 68% CL range is derived from the 1σ boundary of the amplitude fit to the data. Oscillation parameters are constrained to be in the LMA region. The mixing angle is fixed at $\tan^2\theta = 0.44$ because the fit depends only very weekly on it.

[36] AHARMIM 05A obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (ARAKI 05). *CPT* invariance is assumed. AHARMIM 05A also quotes $\Delta(m^2) = (8.0^{+0.6}_{-0.4})\times10^{-5}$ eV^2 as the error enveloping the 68% CL two-dimensional region.

[37] AHARMIM 05A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in figure 35a of AHARMIM 05A. AHARMIM 05A also quotes $\Delta(m^2) = (6.5^{+4.4}_{-2.3})\times10^{-5}$ eV^2 as the error enveloping the 68% CL two-dimensional region.

[38] ARAKI 05 obtained this result by a two-neutrino oscillation analysis using KamLAND and solar neutrino data. *CPT* invariance is assumed. The 1σ error shown here is provided by the KamLAND collaboration. The error quoted in ARAKI 05, $\Delta(m^2) = (7.9^{+0.6}_{-0.5})\times10^{-5}$, envelops the 68% CL two-dimensional region.

[39] AHMED 04A obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (EGUCHI 03). *CPT* invariance is assumed. AHMED 04A also quotes $\Delta(m^2) = (7.1^{+1.2}_{-0.6})\times10^{-5}$ eV^2 as the error enveloping the 68% CL two-dimensional region.

[40] AHMED 04A obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 5(a) of AHMED 04A. The best-fit point is $\Delta(m^2) = 6.5\times10^{-5}$ eV^2, $\tan^2\theta = 0.40$ ($\sin^2 2\,\theta = 0.82$).

[41] SMY 04 obtained this result by a two-neutrino oscillation analysis using solar neutrino and KamLAND data (IANNI 03). *CPT* invariance is assumed.

[42] SMY 04 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The 1σ errors are read from Fig. 6(a) of SMY 04.

[43] SMY 04 obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande and SNO (AHMAD 02 and AHMAD 02B) solar neutrino data. The 1σ errors are read from Fig. 6(a) of SMY 04.

[44] AHMAD 02B obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4(b) of AHMAD 02B. The best fit point is $\Delta(m^2) = 5.0\times10^{-5}$ eV^2 and $\tan\theta = 0.34$ ($\sin^2 2\,\theta = 0.76$).

[45] FUKUDA 02 obtained this result by a two-neutrino oscillation analysis using the data from all solar neutrino experiments. The listed range of the parameter envelops the 95% CL two-dimensional region shown in Fig. 4 of FUKUDA 02. The best fit point is $\Delta(m^2) = 6.9\times10^{-5}$ eV^2 and $\tan^2\theta = 0.38$ ($\sin^2 2\,\theta = 0.80$).

$\sin^2(\theta_{23})$

The reported limits below correspond to the projection onto the $\sin^2(\theta_{23})$ axis of the 90% CL contours in the $\sin^2(\theta_{23}) - \Delta m^2_{32}$ plane presented by the authors. Unless otherwise specified, the limits are 90% CL and the reported uncertainties are 68% CL.

If an experiment reports $\sin^2(2\,\theta_{23})$ we convert the value to $\sin^2(\theta_{23})$.

[1] ABBASI 23 uses atmospheric neutrino data measured between 2011 and 2019 with the low-energy subdetector DeepCore of the IceCube neutrino telescope. Supersedes AARTSEN 18A.

[2] ABE 23F results are based on data collected between 2010 and 2020 in (anti)neutrino mode and include a neutrino beam exposure of 1.97×10^{21} (1.63×10^{21}) protons on target. Supersedes ABE 20F.

[3] ACERO 22 uses data from Jun 29, 2016 to Feb 26, 2019 (12.5×10^{20} POT) and Feb 6, 2014 to Mar 20, 2020 (13.6×10^{20} POT). Best fit for octant I (lower octant) is 0.46 for both normal and inverted mass orderings. Supersedes ACERO 19.

[4] ADAMSON 20A uses the complete dataset from MINOS and MINOS+ experiments. The data were collected using a total exposure of 23.76×10^{20} protons on target and 60.75 kton-yr exposure to atmospheric neutrinos. Supersedes ADAMSON 14.

[5] ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the three parameters, Δm^2_{32}, $\sin^2(\theta_{23})$, and δ, while the solar parameters and $\sin^2(\theta_{13})$ are fixed to $\Delta m^2_{21} = (7.53 \pm 0.18) \times 10^{-5}$ eV^2, $\sin^2(\theta_{12}) = 0.304 \pm 0.014$, and $\sin^2(\theta_{13}) = 0.0219 \pm 0.0012$.

[6] ABE 23D uses the same dataset as ABE 23F. The measurement of $\sin^2(\theta_{23})$ is performed independently for ν_μ and $\overline{\nu}_\mu$.

[7] ABE 21A results are based on 1.49×10^{21} POT in neutrino mode and 1.64×10^{21} POT in antineutrino mode.

[8] SALAS 21 reports results of a global fit to neutrino oscillation data available at the time of the Neutrino 2020 conference.

[9] AARTSEN 20 uses the data taken between May 2012 and April 2014 with the low-energy subdetector DeepCore of the IceCube neutrino telescope. The reconstructed energy range is between 4 (5) and 90 (80) GeV for the main (confirmatory) analysis. Though the observed best-fit is in the lower octant for both mass orderings, a substantial range of $\sin^2(\theta_{23}) > 0.5$ is still compatible with the observed data for both mass orderings.

[10] ABE 20F results are based on data collected between 2009 and 2018 in (anti)neutrino mode and include a neutrino beam exposure of 1.49×10^{21} (1.64×10^{21}) protons on target. Supersedes ABE 18G.

[11] ESTEBAN 20A reports results of a global fit to neutrino oscillation data available at the time of the Neutrino2020 conference.

[12] AARTSEN 19C uses three years (April 2012 – May 2015) of neutrino data from full sky with reconstructed energies between 5.6 and 56 GeV, measured with the low-energy subdetector DeepCore of the IceCube neutrino telescope. AARTSEN 19C adopts looser event selection criteria to prioritize the efficiency of selecting neutrino events, different from tighter event selection criteria which closely follow the criteria used by AARTSEN 18A to measure the ν_μ disappearance.

[13] ACERO 19 is based on a sample size of 12.33×10^{20} protons on target. The fit combines both antineutrino and neutrino data to extract the oscillation parameters. The results favor the normal mass ordering by 1.9 σ and θ_{23} values in octant II by 1.6 σ. Supersedes ACERO 18.

[14] Errors are from normal mass ordering and θ_{13} octant II fits.

[15] ALBERT 19 measured the oscillation parameters of atmospheric neutrinos with the ANTARES deep sea neutrino telescope using the data taken from 2007 to 2016 (2830 days of total live time). Supersedes ADRIAN-MARTINEZ 12.

[16] AARTSEN 18A uses three years (April 2012 – May 2015) of neutrino data from full sky with reconstructed energies between 5.6 and 56 GeV, measured with the low-energy subdetector DeepCore of the IceCube neutrino telescope. AARTSEN 18A also reports the best fit result for the inverted mass ordering as $\Delta m^2_{32} = -2.32 \times 10^{-3}$ eV^2 and $\sin^2(\theta_{23}) = 0.51$. Uncertainties for the inverted mass ordering fits were not provided. Supersedes AARTSEN 15A.

[17] ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the four parameters, Δm^2_{32}, $\sin^2\theta_{23}$, $\sin^2\theta_{13}$, and δ, while the solar parameters are fixed to $\Delta m^2_{21} = (7.53 \pm 0.18) \times 10^{-5}$ eV^2 and $\sin^2\theta_{12} = 0.304 \pm 0.014$.

[18] ABE 18G data prefers normal mass ordering is with a posterior probability of 87%. Supersedes ABE 17F.

[19] ACERO 18 performs a joint fit to the data for ν_μ disappearance and ν_e appearance. The overall best fit favors normal mass ordering and θ_{23} in octant II. No 1σ confidence intervals are presented for the inverted mass ordering scenarios. Superseded by ACERO 19.

[20] Errors are from the projections of the 68% contour on 2D plot of Δm^2 versus $\sin^2(\theta_{23})$. ABE 17F supersedes ABE 17A. Superseded by ABE 18G.

[21] Superseded by ACERO 18.

[22] ABE 16D reports oscillation results using $\overline{\nu}_\mu$ disappearance in an off-axis beam.

[23] ADAMSON 16A obtains $\sin^2(\theta_{23})$ in the 68% C.L. range [0.38, 0.65] ([0.37, 0.64]), with two statistically degenerate best-fit values of 0.44 and 0.59 (0.44 and 0.59) for normal (inverted) mass ordering. Superseded by ADAMSON 17A.

[24] AARTSEN 15A obtains this result by a three-neutrino oscillation analysis using 10–100 GeV muon neutrino sample from a total of 953 days of measurement with the low-energy subdetector DeepCore of the IceCube neutrino telescope. Superseded by AARTSEN 18A.

[25] ABE 14 results are based on ν_μ disappearance using three-neutrino oscillation fit. The confidence intervals are derived from one dimensional profiled likelihoods. Superseded by ABE 17A.

[26] ADAMSON 14 uses a complete set of accelerator and atmospheric data. The analysis combines the ν_μ disappearance and ν_e appearance data using three-neutrino oscillation fit. The fit results are obtained for normal and inverted mass ordering assumptions. The best fit is for first θ_{23} octant and inverted mass ordering.

[27] FORERO 14 performs a global fit to neutrino oscillations using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.

[28] GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as 68% CL intervals of 0.433–0.496 or 0.530–0.594 for normal and 0.514–0.612 for inverted mass ordering.

[29] AARTSEN 13B obtained this result by a two-neutrino oscillation analysis using 20–100 GeV muon neutrino sample from a total of 318.9 days of live-time measurement with the low-energy subdetector DeepCore of the IceCube neutrino telescope.

[30] The best fit value is $\sin^2(\theta_{23}) = 0.514 \pm 0.082$. Superseded by ABE 14.

[31] ADAMSON 13B obtained this result from ν_μ and $\overline{\nu}_\mu$ disappearance using ν_μ (10.71×10^{20} POT) and $\overline{\nu}_\mu$ (3.36×10^{20} POT) beams, and atmospheric (37.88kton-years) data

from MINOS The fit assumed two-flavor neutrino hypothesis and identical ν_μ and $\overline{\nu}_\mu$ oscillation parameters. Superseded by ADAMSON 14.

[32] ABE 12A obtained this result by a two-neutrino oscillation analysis. The best-fit point is $\sin^2(2\theta_{23}) = 0.98$.

[33] ADAMSON 12 is a two-neutrino oscillation analysis using antineutrinos. The best fit value is $\sin^2(2\theta_{23}) = 0.95^{+0.10}_{-0.11} \pm 0.01$.

[34] ADAMSON 12B obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 37.9 kton-yr atmospheric neutrino data with the MINOS far detector.

[35] The best fit point is $\Delta m^2 = 0.0019$ eV^2 and $\sin^2 2\theta = 0.99$. The 90% single-parameter confidence interval at the best fit point is $\sin^2 2\theta > 0.86$.

[36] The data are separated into pure samples of νs and $\overline{\nu}$s, and separate oscillation parameters for νs and $\overline{\nu}$s are fit to the data. The best fit point is (Δm^2, $\sin^2 2\theta$) = (0.0022 eV^2, 0.99) and ($\Delta\overline{m}^2$, $\sin^2 2\overline{\theta}$) = (0.0016 eV^2, 1.00). The quoted result is taken from the 90% C.L. contour in the (Δm^2, $\sin^2 2\theta$) plane obtained by minimizing the four parameter log-likelihood function with respect to the other oscillation parameters.

[37] ADRIAN-MARTINEZ 12 measured the oscillation parameters of atmospheric neutrinos with the ANTARES deep sea neutrino telescope using the data taken from 2007 to 2010 (863 days of total live time). Superseded by ALBERT 19.

[38] ABE 11C obtained this result by a two-neutrino oscillation analysis using the Super-Kamiokande-I+II+III atmospheric neutrino data. ABE 11C also reported results under a two-neutrino disappearance model with separate mixing parameters between ν and $\overline{\nu}$, and obtained $\sin^2 2\theta > 0.93$ for ν and $\sin^2 2\theta > 0.83$ for $\overline{\nu}$ at 90% C.L.

[39] ADAMSON 11B obtained this result by a two-neutrino oscillation analysis of antineutrinos in an antineutrino enhanced beam with 1.71×10^{20} protons on target. This results is consistent with the neutrino measurements of ADAMSON 11 at 2% C.L.

[40] WENDELL 10 obtained this result ($\sin^2\theta_{23} = 0.407$–$0.583$) by a three-neutrino oscillation analysis using the Super-Kamiokande-I+II+III atmospheric neutrino data, assuming $\theta_{13} = 0$ but including the solar oscillation parameters Δm^2_{21} and $\sin^2\theta_{12}$ in the fit.

[41] WENDELL 10 obtained this result ($\sin^2\theta_{23} = 0.43$–0.61) by a three-neutrino oscillation analysis with one mass scale dominance ($\Delta m^2_{21} = 0$) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06A result.

[42] WENDELL 10 obtained this result ($\sin^2\theta_{23} = 0.44$–0.63) by a three-neutrino oscillation analysis with one mass scale dominance ($\Delta m^2_{21} = 0$) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06A result.

[43] ADAMSON 06 obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 4.54 kton yr atmospheric neutrino data with the MINOS far detector.

[44] Supercedes ALIU 05.

[45] MICHAEL 06 best fit is for maximal mixing. See also ADAMSON 08.

[46] The best fit is for maximal mixing.

[47] ALLISON 05 result is based upon atmospheric neutrino interactions including upward-stopping muons, with an exposure of 5.9 kton yr. From a two-flavor oscillation analysis the best-fit point is $\Delta m^2 = 0.0017$ eV^2 and $\sin^2(2\theta) = 0.97$.

[48] ASHIE 05 obtained this result by a two-neutrino oscillation analysis using 92 kton yr atmospheric neutrino data from the complete Super-Kamiokande I running period.

[49] AMBROSIO 04 obtained this result, without using the absolute normalization of the neutrino flux, by combining the angular distribution of upward through-going muon tracks with $E_\mu > 1$ GeV, N_{low} and N_{high}, and the numbers of InDown + UpStop and InUp events. Here, N_{low} and N_{high} are the number of events with reconstructed neutrino energies < 30 GeV and > 130 GeV, respectively. InDown and InUp represent events with downward and upward-going tracks starting inside the detector due to neutrino interactions, while UpStop represents entering upward-going tracks which stop in the detector. The best fit is for maximal mixing.

[50] ASHIE 04 obtained this result from the L(flight length)/E(estimated neutrino energy) distribution of ν_μ disappearance probability, using the Super-Kamiokande-I 1489 live-day atmospheric neutrino data.

[51] There are several islands of allowed region from this K2K analysis, extending to high values of Δm^2. We only include the one that overlaps atmospheric neutrino analyses. The best fit is for maximal mixing.

[52] AMBROSIO 03 obtained this result on the basis of the ratio $R = N_{low}/N_{high}$, where N_{low} and N_{high} are the number of upward through-going muon events with reconstructed neutrino energy < 30 GeV and > 130 GeV, respectively. The data came from the full detector run started in 1994. The method of FELDMAN 98 is used to obtain the limits.

[53] AMBROSIO 03 obtained this result by using the ratio R and the angular distribution of the upward through-going muons. R is given in the previous note and the angular distribution is reported in AMBROSIO 01. The method of FELDMAN 98 is used to obtain the limits. The best fit is to maximal mixing.

[54] SANCHEZ 03 is based on an exposure of 5.9 kton yr. The result is obtained using a likelihood analysis of the neutrino L/E distribution for a selection μ flavor sample while the e-flavor sample provides flux normalization. The method of FELDMAN 98 is used to obtain the allowed region. The best fit is $\sin^2(2\theta) = 0.97$.

[55] AMBROSIO 01 result is based on the angular distribution of upward through-going muon tracks with $E_\mu > 1$ GeV. The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration is 6.17 years. The best fit is obtained outside the physical region. The method of FELDMAN 98 is used to obtain the limits. The best fit is for maximal mixing.

[56] AMBROSIO 01 result is based on the angular distribution and normalization of upward through-going muon tracks with $E_\mu > 1$ GeV. See the previous footnote.

[57] FUKUDA 99C obtained this result from a total of 537 live days of upward through-going muon data in Super-Kamiokande between April 1996 to January 1998. With a threshold of $E_\mu > 1.6$ GeV, the observed flux is $(1.74 \pm 0.07 \pm 0.02) \times 10^{-13}$ cm^{-2}s^{-1}sr^{-1}. The best fit is $\sin^2(2\theta) = 0.95$.

[58] FUKUDA 99D obtained this result from a simultaneous fitting to zenith angle distributions of upward-stopping and through-going muons. The flux of upward-stopping muons of minimum energy of 1.6 GeV measured between April 1996 and January 1998 is $(0.39 \pm 0.04 \pm 0.02) \times 10^{-13}$ cm^{-2}s^{-1}sr^{-1}. This is compared to the expected flux of $(0.73 \pm 0.16$ (theoretical error)$) \times 10^{-13}$ cm^{-2}s^{-1}sr^{-1}. The best fit is to maximal mixing.

[59] FUKUDA 99D obtained this result from the zenith dependence of the upward-stopping/through-going flux ratio. The best fit is to maximal mixing.

[60] FUKUDA 98C obtained this result by an analysis of 33.0 kton yr atmospheric neutrino data. The best fit is for maximal mixing.

[61] HATAKEYAMA 98 obtained this result from a total of 2456 live days of upward-going muon data in Kamiokande between December 1985 and May 1995. With a threshold of $E_\mu > 1.6$ GeV, the observed flux of upward through-going muons is $(1.94 \pm 0.10^{+0.07}_{-0.06}) \times 10^{-13}$ cm^{-2}s^{-1}sr^{-1}. This is compared to the expected flux of $(2.46 \pm 0.54$ (theoretical error)$) \times 10^{-13}$ cm^{-2}s^{-1}sr^{-1}. The best fit is for maximal mixing.

[62] HATAKEYAMA 98 obtained this result from a combined analysis of Kamiokande contained events (FUKUDA 94) and upward going muon events. The best fit is $\sin^2(2\theta) = 0.95$.

[63] FUKUDA 94 obtained the result by a combined analysis of sub- and multi-GeV atmospheric neutrino events in Kamiokande. The best fit is for maximal mixing.

Δm^2_{32}

The sign of Δm^2_{32} is not known at this time. If given, values are shown separately for the normal and inverted mass ordering. Unless otherwise specified, the ranges below correspond to the projection onto the Δm^2_{32} axis of the 90% CL contours in the $\sin^2(2\theta_{23}) - \Delta m^2_{32}$ plane presented by the authors. If uncertainties are reported with the value, they correspond to one standard deviation uncertainty.

5–25	[74] FUKUDA	94	KAMI	Kamiokande

[1] ABBASI 23 uses atmospheric neutrino data measured between 2011 and 2019 with the low-energy subdetector DeepCore of the IceCube neutrino telescope. Supersedes AARTSEN 18A.

[2] ABE 23F results are based on data collected between 2010 and 2020 in (anti)neutrino mode and include a neutrino beam exposure of 1.97×10^{21} (1.63×10^{21}) protons on target. Supersedes ABE 20F.

[3] ABE 23F reports $\Delta m^2_{13}=(2.463^{+0.042}_{-0.056})\times10^{-3}$ eV^2 for inverted mass ordering. We convert to Δm^2_{32} using PDG 23 value of $\Delta m^2_{21}=(7.53\pm0.18)\times10^{-5}$ eV^2.

[4] AN 23 reports results derived from the complete data set collected by the Daya-Bay experiment, corresponding to 3158 days of operation, resulting in 5.55×10^6 $\overline{\nu}_e$ candidate events. Solar oscillation parameters are fixed in the analysis to $\sin^2(\theta_{12})=0.307\pm0.013$, $\Delta m^2_{21}=(7.53\pm0.18)\times10^{-5}$ eV^2 from PDG 20. Supersedes ADEY 18A.

[5] ACERO 22 uses data from Jun 29, 2016 to Feb 26, 2019 (12.5×10^{20} POT) and Feb 6, 2014 to Mar 20, 2020 (13.6×10^{20} POT). For normal mass ordering and θ_{23} octant I (lower octant), best fit is 0.00239 eV^2; for inverted mass ordering and octant I, best fit is -0.00244 eV^2. Supersedes ACERO 19.

[6] ADAMSON 20A uses the complete dataset from MINOS and MINOS+ experiments. The data were collected using a total exposure of 23.76×10^{20} protons on target and 60.75 kton-yr exposure to atmospheric neutrinos. Supersedes ADAMSON 14.

[7] ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the three parameters, Δm^2_{32}, $\sin^2(\theta_{23})$, and δ, while the solar parameters and $\sin^2(\theta_{13})$ are fixed to $\Delta m^2_{21}=(7.53\pm0.18)\times10^{-5}$ eV^2, $\sin^2(\theta_{12})=0.304\pm0.014$, and $\sin^2(\theta_{13})=0.0219\pm0.0012$.

[8] BAK 18 reports results of the RENO experiment using about 2200 live-days of data taken with detectors placed at 410.6 and 1445.7 m from reactors of the Hanbit Nuclear Power Plant. We convert the results to Δm^2_{32} using the PDG 18 values of $\sin^2\theta_{12}=0.307^{+0.013}_{-0.012}$ and $\Delta m^2_{21}=(7.53\pm0.18)\times10^{-5}$ eV^2. Supersedes SEO 18.

[9] ABE 23D uses the same dataset as ABE 23F. The measurement of Δm^2_{32} is performed independently for ν_μ and $\overline{\nu}_\mu$.

[10] ABE 21A results are based on 1.49×10^{21} POT in neutrino mode and 1.64×10^{21} POT in antineutrino mode.

[11] ABE 20F results are based on data collected between 2009 and 2018 in (anti)neutrino mode and include a neutrino beam exposure of 1.49×10^{21} (1.64×10^{21}) protons on target. Supersedes ABE 18G.

[12] ABE 20F reports $\Delta m^2_{13}=(2.43\pm0.07)\times10^{-3}$ eV^2 for inverted mass ordering. We convert to Δm^2_{32} using PDG 20 value of $\Delta m^2_{21}=(7.53\pm0.18)\times10^{-5}$ eV^2.

[13] ESTEBAN 20A reports results of a global fit to neutrino oscillation data available at the time of the Neutrino2020 conference.

[14] AARTSEN 19C uses three years (April 2012 – May 2015) of neutrino data from full sky with reconstructed energies between 5.6 and 56 GeV, measured with the low-energy subdetector DeepCore of the IceCube neutrino telescope. AARTSEN 19C adopts looser event selection criteria to prioritize the efficiency of selecting neutrino events, different from tighter event selection criteria which closely follow the criteria used by AARTSEN 18A to measure the ν_μ disappearance.

[15] ACERO 19 is based on a sample size of 12.33×10^{20} protons on target. The fit combines both antineutrino and neutrino data to extract the oscillation parameters. The results favor the normal mass ordering by 1.9 σ and θ_{23} values in octant II by 1.6 σ. Superseded by ACERO 22.

[16] ALBERT 19 measured the oscillation parameters of atmospheric neutrinos with the ANTARES deep sea neutrino telescope using the data taken from 2007 to 2016 (2830 days of total live time). Supersedes ADRIAN-MARTINEZ 12.

[17] AARTSEN 18A uses three years (April 2012 – May 2015) of neutrino data from full sky with reconstructed energies between 5.6 and 56 GeV, measured with the low-energy subdetector DeepCore of the IceCube neutrino telescope. AARTSEN 18A also reports the best fit values for the inverted mass ordering as $\Delta m^2_{32}=-2.32\times10^{-3}$ eV^2 and $\sin^2(\theta_{23})=0.51$. Uncertainties for the inverted mass ordering fits were not provided. Supersedes AARTSEN 15A.

[18] ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the four parameters, Δm^2_{32}, $\sin^2\theta_{23}$, $\sin^2\theta_{13}$, and δ, while the solar parameters are fixed to $\Delta m^2_{21}=(7.53\pm0.18)\times10^{-5}$ eV^2 and $\sin^2\theta_{12}=0.304\pm0.014$.

[19] ABE 18G data prefers normal ordering with a posterior probability of 87%. Supersedes ABE 17F.

[20] ABE 18G reports $\Delta m^2_{13}=(2.432 \pm 0.070) \times 10^{-3}$ eV^2 for inverted mass ordering. We convert to Δm^2_{32} using PDG 18 value of $\Delta m^2_{21}=(7.53 \pm 0.18) \times 10^{-5}$ eV^2.

[21] ACERO 18 performs a joint fit to the data for ν_μ disappearance and ν_e appearance. The overall best fit favors normal mass ordering and θ_{23} in octant II. No 1σ confidence intervals are presented for the inverted mass ordering scenarios. Superseded by ACERO 19.

[22] The error for octant I is taken from the result for octant II.

[23] ADEY 18A reports results from analysis of 1958 days of data taking with the Daya-Bay experiment, with 3.9×10^6 $\overline{\nu}_e$ candidates. The fit to the data gives $\Delta m^2_{ee} = (2.522^{+0.068}_{-0.070}) \times 10^{-3}$ eV^2. Solar oscillation parameters are fixed in the analysis using the global averages, $\sin^2(\theta_{12}) = 0.307^{+0.013}_{-0.012}$, $\Delta m^2_{21} = (7.53 \pm 0.18) \times 10^{-5}$ eV^2, from PDG 18. Supersedes AN 17A.

[24] AGAFONOVA 18 assumes maximal θ_{23} mixing.

[25] SEO 18 reports result of the RENO experiment from a rate and shape analysis of 500 days of data. A simultaneous fit to θ_{13} and Δm^2_{ee} yields $\Delta m^2_{ee} = (2.62^{+0.21+0.12}_{-0.23-0.13}) \times 10^{-3}$ eV^2. We convert the results to Δm^2_{32} using the PDG 18 values of $\sin^2\theta_{12}$ and Δm^2_{21}. SEO 18 is a detailed description of the results published in CHOI 16, which it supersedes. Superseded by BAK 18

[26] ABE 17F confidence intervals are obtained using a frequentist analysis including θ_{13} constraint from reactor experiments. Bayesian intervals based on Markov Chain Monte Carlo method are also provided by the authors. Superseded by ABE 18G.

[27] Superseded by ACERO 18.

[28] AN 17A report results from combined rate and spectral shape analysis of 1230 days of data taken with the Daya Bay reactor experiment. The data set contains more than 2.5×10^6 inverse beta-decay events with neutron capture on Gd. The fit to the data gives $\Delta^2_{ee}=(2.50 \pm 0.06 \pm 0.06) \times 10^{-3}$ eV. Superseded by ADEY 18A.

[29] ABE 16D reports oscillation results using $\overline{\nu}_\mu$ disappearance in an off-axis beam.

[30] Superseded by ADAMSON 17A.

[31] CHOI 16 reports result of the RENO experiment from a rate and shape analysis of 500 days of data. A simultaneous fit to θ_{13} and Δm^2_{ee} yields $\Delta m^2_{ee} = (2.62^{+0.21+0.12}_{-0.23-0.13}) \times 10^{-3}$ eV. We convert the results to Δm^2_{32} using PDG 18 values of $\sin^2(\theta_{12})$ and Δm^2_{21}.

[32] AARTSEN 15A obtains this result by a three-neutrino oscillation analysis using 10–100 GeV muon neutrino sample from a total of 953 days of measurements with the low-energy subdetector DeepCore of the IceCube neutrino telescope. Superseded by AARTSEN 18A.

[33] AGAFONOVA 15A result is based on 5 $\nu_\mu \rightarrow \nu_\tau$ appearance candidates with an expected background of 0.25 $\pm$ 0.05 events. The best fit is for $\Delta m^2_{32}=3.3 \times 10^{-3}$ eV^2.

[34] AN 15 uses all eight identical detectors, with four placed near the reactor cores and the remaining four at the far hall to determine prompt energy spectra. The results correspond to the exposure of 6.9×10^5 GW$_{th}$-ton-days. They derive $\Delta m^2_{ee} = (2.42 \pm 0.11) \times 10^{-3}$ eV^2. Assuming the normal (inverted) ordering, the fitted $\Delta m^2_{32} = (2.37 \pm 0.11) \times 10^{-3}$ ($(2.47 \pm 0.11) \times 10^{-3}$) eV^2. Superseded by AN 17A.

[35] ABE 14 results are based on ν_μ disappearance using three-neutrino oscillation fit. The confidence intervals are derived from one dimensional profiled likelihoods. In ABE 14 the inverted mass ordering result is reported as $\Delta m^2_{13} = (2.48 \pm 0.10) \times 10^{-3}$ eV^2 which we converted to Δm^2_{32} by adding PDG 14 value of $\Delta m^2_{21} = (7.53 \pm 0.18) \times 10^{-5}$ eV^2. Superseded by ABE 17C.

[36] ADAMSON 14 uses a complete set of accelerator and atmospheric data. The analysis combines The analysis combines the ν_μ disappearance and ν_e appearance data using three-neutrino oscillation fit. The fit results are obtained for normal and inverted mass ordering assumptions.

[37] AN 14 uses six identical detectors, with three placed near the reactor cores (flux-weighted baselines of 512 and 561 m) and the remaining three at the far hall (at the flux averaged distance of 1579 m from all six reactor cores) to determine prompt energy spectra and derive $\Delta m^2_{ee} = (2.59^{+0.19}_{-0.20}) \times 10^{-3}$ eV^2. Assuming the normal (inverted) ordering, the fitted $\Delta m^2_{32} = (2.54^{+0.19}_{-0.20}) \times 10^{-3}$ ($(2.64^{+0.19}_{-0.20}) \times 10^{-3}$) eV^2. Superseded by AN 15.

[38] FORERO 14 performs a global fit to Δm^2_{31} using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.

[39] GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as $(2.460 \pm 0.046) \times 10^{-3}$ eV^2 for normal and $(2.445^{+0.047}_{-0.045}) \times 10^{-3}$ eV^2 for inverted mass ordering.

[40] The value for normal mass ordering is actually a measurement of Δm^2_{31} which differs from Δm^2_{32} by a much smaller value of Δm^2_{12}.

[41] AARTSEN 13B obtained this result by a two-neutrino oscillation analysis using 20–100 GeV muon neutrino sample from a total of 318.9 days of live-time measurement with the low-energy subdetector DeepCore of the IceCube neutrino telescope.

[42] Based on the observation of 58 ν_μ events with 205 $\pm$ 17(syst) expected in the absence of neutrino oscillations. Superseded by ABE 14.

[43] ADAMSON 13B obtained this result from ν_μ and $\overline{\nu}_\mu$ disappearance using ν_μ (10.71×10^{20} POT) and $\overline{\nu}_\mu$ (3.36×10^{20} POT) beams, and atmospheric (37.88 kton-years) data from MINOS. The fit assumed two-flavor neutrino hypothesis and identical ν_μ and $\overline{\nu}_\mu$ oscillation parameters.

[44] ABE 12A obtained this result by a two-neutrino oscillation analysis. The best-fit point is $\Delta m^2_{32} = 2.65 \times 10^{-3}$ eV^2.

[45] ADAMSON 12 is a two-neutrino oscillation analysis using antineutrinos.

[46] ADAMSON 12B obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 37.9 kton·yr atmospheric neutrino data with the MINOS far detector.

[47] The 90% single-parameter confidence interval at the best fit point is $\Delta m^2 = 0.0019 \pm 0.0004$ eV^2.

[48] The data are separated into pure samples of νs and $\overline{\nu}$s, and separate oscillation parameters for νs and $\overline{\nu}$s are fit to the data. The best fit point is (Δm^2, $\sin^2 2\theta$) = (0.0022 eV^2, 0.99) and ($\Delta\overline{m}^2$, $\sin^2 2\overline{\theta}$) = (0.0016 eV^2, 1.00). The quoted result is taken from the 90% C.L. contour in the (Δm^2, $\sin^2 2\theta$) plane obtained by minimizing the four parameter log-likelihood function with respect to the other oscillation parameters.

[49] ADRIAN-MARTINEZ 12 measured the oscillation parameters of atmospheric neutrinos with the ANTARES deep sea neutrino telescope using the data taken from 2007 to 2010 (863 days of total live time). Superseded by ALBERT 19

[50] ABE 11C obtained this result by a two-neutrino oscillation analysis with separate mixing parameters between neutrinos and antineutrinos, using the Super-Kamiokande-I+II+III atmospheric neutrino data. The corresponding 90% CL neutrino oscillation parameter range obtained from this analysis is $\Delta m^2 = 1.7$–3.0×10^{-3} eV^2.

[51] ADAMSON 11B obtained this result by a two-neutrino oscillation analysis of antineutrinos in an antineutrino enhanced beam with 1.71×10^{20} protons on target. This results is consistent with the neutrino measurements of ADAMSON 11 at 2% C.L.

[52] ADAMSON 11C obtains this result based on a study of antineutrinos in a neutrino beam and assumes maximal mixing in the two-flavor approximation.

[53] WENDELL 10 obtained this result by a three-neutrino oscillation analysis with one mass scale dominance ($\Delta m^2_{21} = 0$) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06A result.

[54] ADAMSON 06 obtained this result by a two-neutrino oscillation analysis of the L/E distribution using 4.54 kton yr atmospheric neutrino data with the MINOS far detector.

[55] The best fit in the physical region is for $\Delta m^2 = 2.8 \times 10^{-3}$ eV^2.

[56] Supercedes ALIU 05.

[57] MICHAEL 06 best fit is 2.74×10^{-3} eV^2. See also ADAMSON 08.

[58] ALLISON 05 result is based on an atmospheric neutrino observation with an exposure of 5.9 kton yr. From a two-flavor oscillation analysis the best-fit point is $\Delta m^2 = 0.0017$ eV^2 and $\sin^2 2\,\theta = 0.97$.

[59] ASHIE 05 obtained this result by a two-neutrino oscillation analysis using 92 kton yr atmospheric neutrino data from the complete Super-Kamiokande I running period. The best fit is for $\Delta m^2 = 2.1 \times 10^{-3}$ eV^2.

[60] AMBROSIO 04 obtained this result, without using the absolute normalization of the neutrino flux, by combining the angular distribution of upward through-going muon tracks with $E_\mu > 1$ GeV, N$_{low}$ and N$_{high}$, and the numbers of InDown + UpStop and InUp events. Here, N$_{low}$ and N$_{high}$ are the number of events with reconstructed neutrino energies < 30 GeV and > 130 GeV, respectively. InDown and InUp represent events with downward and upward-going tracks starting inside the detector due to neutrino interactions, while UpStop represents entering upward-going tracks which stop in the detector. The best fit is for $\Delta m^2 = 2.3 \times 10^{-3}$ eV^2.

[61] ASHIE 04 obtained this result from the L(flight length)/E(estimated neutrino energy) distribution of ν_μ disappearance probability, using the Super-Kamiokande-I 1489 live-day atmospheric neutrino data. The best fit is for $\Delta m^2 = 2.4 \times 10^{-3}$ eV^2.

[62] There are several islands of allowed region from this K2K analysis, extending to high values of Δm^2. We only include the one that overlaps atmospheric neutrino analyses. The best fit is for $\Delta m^2 = 2.8 \times 10^{-3}$ eV^2.

[63] AMBROSIO 03 obtained this result on the basis of the ratio R = N$_{low}$/N$_{high}$, where N$_{low}$ and N$_{high}$ are the number of upward through-going muon events with reconstructed neutrino energy < 30 GeV and > 130 GeV, respectively. The data came from the full detector run started in 1994. The method of FELDMAN 98 is used to obtain the limits. The best fit is for $\Delta m^2 = 2.5 \times 10^{-3}$ eV^2.

[64] AMBROSIO 03 obtained this result by using the ratio R and the angular distribution of the upward through-going muons. R is given in the previous note and the angular distribution is reported in AMBROSIO 01. The method of FELDMAN 98 is used to obtain the limits. The best fit is for $\Delta m^2 = 2.5 \times 10^{-3}$ eV^2.

[65] SANCHEZ 03 is based on an exposure of 5.9 kton yr. The result is obtained using a likelihood analysis of the neutrino L/E distribution for a selection μ flavor sample while the e-flavor sample provides flux normalization. The method of FELDMAN 98 is used to obtain the allowed region. The best fit is for $\Delta m^2 = 5.2 \times 10^{-3}$ eV^2.

[66] AMBROSIO 01 result is based on the angular distribution of upward through-going muon tracks with $E_\mu > 1$ GeV. The data came from three different detector configurations, but the statistics is largely dominated by the full detector run, from May 1994 to December 2000. The total live time, normalized to the full detector configuration is 6.17 years. The best fit is obtained outside the physical region. The method of FELDMAN 98 is used to obtain the limits.

[67] AMBROSIO 01 result is based on the angular distribution and normalization of upward through-going muon tracks with $E_\mu > 1$ GeV. See the previous footnote.

[68] FUKUDA 99C obtained this result from a total of 537 live days of upward through-going muon data in Super-Kamiokande between April 1996 to January 1998. With a threshold of $E_\mu > 1.6$ GeV, the observed flux is $(1.74 \pm 0.07 \pm 0.02) \times 10^{-13}$ cm^{-2}s^{-1}sr^{-1}. The best fit is for $\Delta m^2 = 5.9 \times 10^{-3}$ eV^2.

[69] FUKUDA 99D obtained this result from a simultaneous fitting to zenith angle distributions of upward-stopping and through-going muons. The flux of upward-stopping muons of minimum energy of 1.6 GeV measured between April 1996 and January 1998 is $(0.39 \pm 0.04 \pm 0.02) \times 10^{-13}$ cm^{-2}s^{-1}sr^{-1}. This is compared to the expected flux of $(0.73 \pm 0.16$ (theoretical error)$) \times 10^{-13}$ cm^{-2}s^{-1}sr^{-1}. The best fit is for $\Delta m^2 = 3.9 \times 10^{-3}$ eV^2.

[70] FUKUDA 99D obtained this result from the zenith dependence of the upward-stopping/through-going flux ratio. The best fit is for $\Delta m^2 = 3.1 \times 10^{-3}$ eV^2.

[71] FUKUDA 98C obtained this result by an analysis of 33.0 kton yr atmospheric neutrino data. The best fit is for $\Delta m^2 = 2.2 \times 10^{-3}$ eV^2.

[72] HATAKEYAMA 98 obtained this result from a total of 2456 live days of upward-going muon data in Kamiokande between December 1985 and May 1995. With a threshold of $E_\mu > 1.6$ GeV, the observed flux of upward through-going muons is $(1.94 \pm 0.10^{+0.07}_{-0.06}) \times 10^{-13}$ cm^{-2}s^{-1}sr^{-1}. This is compared to the expected flux of $(2.46 \pm 0.54$ (theoretical error)$) \times 10^{-13}$ cm^{-2}s^{-1}sr^{-1}. The best fit is for $\Delta m^2 = 2.2 \times 10^{-3}$ eV^2.

[73] HATAKEYAMA 98 obtained this result from a combined analysis of Kamiokande contained events (FUKUDA 94) and upward going muon events. The best fit is for $\Delta m^2 = 13 \times 10^{-3}$ eV^2.

[74] FUKUDA 94 obtained the result by a combined analysis of sub- and multi-GeV atmospheric neutrino events in Kamiokande. The best fit is for $\Delta m^2 = 16 \times 10^{-3}$ eV^2.

sin$^2(\theta_{13})$

At present time direct measurements of sin$^2(\theta_{13})$ are derived from the reactor $\overline{\nu}_e$ disappearance at distances corresponding to the Δm^2_{32} value, i.e. L $\sim$ 1km. Alternatively, limits can also be obtained from the analysis of the solar neutrino data and accelerator-based $\nu_\mu \to \nu_e$ experiments.

If an experiment reports sin$^2(2\theta_{13})$ we convert the value to sin$^2(\theta_{13})$.

[1] ABE 23F results are based on data collected between 2010 and 2020 in (anti)neutrino mode and include a neutrino beam exposure of 1.97×10^{21} (1.63×10^{21}) protons on target.

[2] AN 23 reports results derived from the complete data set collected by the Daya-Bay experiment, corresponding to 3158 days of operation, resulting in 5.55×10^6 $\overline{\nu}_e$ candidate events. Solar oscillation parameters are fixed in the analysis to sin$^2(\theta_{12}) = 0.307 \pm 0.013$, $\Delta m^2_{21} = (7.53 \pm 0.18) \times 10^{-5}$ eV^2 from PDG 20. Supersedes ADEY 18A.

[3] DE-KERRET 20 uses 481 days of data from single detector operation and also 384 days of data with both near and far detectors operating. A rate and shape analysis is performed on combined neutron captures on H and Gd. Supersedes ABE 16B.

[4] SHIN 20 uses the RENO detector and 1500 live days of data. The near (far) detector observed 567,690 (90,747) $\overline{\nu}_e$ candidate events with a delayed neutron capture on hydrogen. The extracted value of sin$^2\theta_{13}$ is consistent with the previous analysis with neutron capture on Gd in BAK 18.

[5] BAK 18 reports results of the RENO experiment using about 2200 live-days of data taken with detectors placed at 410.6 and 1445.7 m from reactors of the Hanbit Nuclear Power Plant. Supersedes SEO 18.

[6] AN 16A uses data from the eight antineutrino detectors (404 days) and six antineutrino detectors (217 days) runs to determine the mixing parameter sin$^2(2\theta_{13})$ using the neutron capture on H only. Supersedes AN 14B.

[7] ABRAHAO 21 uses 865 days of data collected in both near and far detectors with at least one reactor in operation. The analysis is based on a background model independent approach, so called Reactor Rate Modulation, to determine the mixing angle θ_{13}. Adding the background model reduces the uncertainty to 0.0041. Supersedes ABE 16B.

[8] SALAS 21 reports results of a global fit to neutrino oscillation data available at the time of the Neutrino 2020 conference.

[9] ESTEBAN 20A reports results of a global fit to neutrino oscillation data available at the time of the Neutrino2020 conference.

[10] ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the four parameters, Δm^2_{32}, sin$^2\theta_{23}$, sin$^2\theta_{13}$, and δ, while the solar parameters are fixed to $\Delta m^2_{21} = (7.53 \pm 0.18) \times 10^{-5}$ eV^2 and sin$^2\theta_{12} = 0.304 \pm 0.014$.

[11] ADEY 18A reports results from analysis of 1958 days of data taking with the Daya-Bay experiment, with 3.9×10^6 $\overline{\nu}_e$ candidates. The fit to the data gives $\Delta m^2_{ee} = (2.522^{+0.068}_{-0.070}) \times 10^{-3}$ eV^2. Solar oscillation parameters are fixed in the analysis using the global averages, sin$^2(\theta_{12}) = 0.307^{+0.013}_{-0.012}$, $\Delta m^2_{21} = (7.53 \pm 0.18) \times 10^{-5}$ eV^2, from PDG 18. Supersedes AN 17A.

[12] AGAFONOVA 18A reports sin$^2(2\theta_{13}) < 0.43$ at 90% C.L. The result on the sterile neutrino search in the context of 3+1 model is also reported. A 90% C.L. upper limit on sin$^2(2\theta_{\mu e}) = 0.021$ for $\Delta m^2_{41} \geq 0.1$ eV^2 is set.

[13] SEO 18 reports results of the RENO experiment using about 500 days of data, performing a rate and shape analysis. Compared to AHN 12, a significant reduction of the systematic uncertainties is reported. A 3% excess of events near 5 MeV of the prompt energy is observed. SEO 18 is a detailed description of the results published in CHOI 16, which it supersedes. Superseded by BAK 18.

[14] Using T2K data only. For inverted mass ordering, all values of θ_{13} are ruled out at 68% CL.

[15] AN 17A reports results from combined rate and spectral shape analysis of 1230 days of data taken with the Daya Bay reactor experiment. The data set contains more than 2.5×10^6 inverse beta-decay events with neutron capture on Gd. A simultaneous fit to θ_{13} and Δm^2_{ee} is performed. Superseded by ADEY 18A.

[16] ABE 16B uses 455.57 live days of data from a detector 1050 m away from two reactor cores of the Chooz nuclear power station, to determine the mixing parameter $\sin^2(2\theta_{13})$. This analysis uses 7.15 reactor-off days for constraining backgrounds. A rate and shape analysis is performed on combined neutron captures on H and Gd. Supersedes ABE 14H and ABE 13C.

[17] CHOI 16 reports results of the RENO experiment using about 500 days of data, performing a rate and shape analysis. Compared to AHN 12, a significant reduction of the systematic uncertainties is reported. A 3% excess of events near 5 MeV of the prompt energy is observed. Supersedes AHN 12.

[18] AN 15 uses all eight identical detectors, with four placed near the reactor cores and the remaining four at the far hall to determine the mixing angle θ_{13} using the $\overline{\nu}_e$ observed interaction rates with neutron capture on Gd and energy spectra. The result corresponds to the exposure of 6.9×10^5 GW_{th}-ton-days. Superseded by AN 17A.

[19] ABE 14A uses 467.9 live days of one detector, 1050 m away from two reactor cores of the Chooz nuclear power station, to determine the mixing parameter $\sin^2(2\ \theta_{13})$. The Bugey4 data (DECLAIS 94) is used to constrain the neutrino flux. The data set includes 7.24 reactor-off days. A "rate-modulation" analysis is performed. Supercedes ABE 12B.

[20] ABE 14C result is for ν_e appearance and assumes $\Delta m^2_{32} = 2.4 \times 10^{-3}$ eV^2, $\sin^2(\ \theta_{23}) = 0.5$, and $\delta = 0$.

[21] ABE 14H uses 467.9 live days of one detector, 1050 m away from two reactor cores of the Chooz nuclear power station, to determine the mixing parameter $\sin^2(2\ \theta_{13})$. The Bugey4 data (DECLAIS 94) is used to constrain the neutrino flux. The data set includes 7.24 reactor-off days. A rate and shape analysis is performed. Superceded by ABE 16B.

[22] AN 14 uses six identical detectors, with three placed near the reactor cores (flux-weighted baselines of 512 and 561 m) and the remaining three at the far hall (at the flux averaged distance of 1579 m from all six reactor cores) to determine the mixing angle θ_{13} using the $\overline{\nu}_e$ observed interaction rates with neutron capture on Gd and energy spectra. Supersedes AN 13 and superseded by AN 15.

[23] AN 14B uses six identical anti-neutrino detectors with flux-weighted baselines of ~ 500 m and ~ 1.6 km to six power reactors. This rate analysis uses a 217-day data set and neutron capture on protons (not Gd) only. $\Delta m^2_{31} = 2.32 \times 10^{-3}$ eV^2 is assumed. Superseded by AN 16A.

[24] FORERO 14 performs a global fit to neutrino oscillations using solar, reactor, long-baseline accelerator, and atmospheric neutrino data.

[25] GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as $(2.18^{+0.10}_{-0.11}) \times 10^{-2}$ eV^2 for normal and $(2.19^{+0.12}_{-0.10}) \times 10^{-2}$ eV^2 for inverted mass ordering.

[26] ABE 13C uses delayed neutron capture on hydrogen instead of on Gd used previously. The physical volume is thus three times larger. The fit is based on the rate and shape analysis as in ABE 12B. The Bugey4 data (DECLAIS 94) is used to constrain the neutrino flux. Superseded by ABE 16B.

[27] ABE 13E assumes maximal θ_{23} mixing and *CP* phase $\delta = 0$.

[28] ADAMSON 13A results obtained from ν_e appearance, assuming $\delta = 0$, and $\sin^2(2\ \theta_{23}) = 0.957$.

[29] AHARMIM 13 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{32} fixed to 2.45×10^{-3} eV^2, using global solar neutrino data. AHARMIM 13 global solar neutrino data include SNO's all-phases-combined analysis results on the total active ^{8}B neutrino flux and energy-dependent ν_e survival probability parameters, measurements of Cl (CLEVELAND 98), Ga (ABDURASHITOV 09 which contains combined analysis with GNO (ALTMANN 05 and Ph.D. thesis of F. Kaether)), and ^{7}Be (BELLINI 11A) rates, and ^{8}B solar-neutrino recoil electron measurements of SK-I (HOSAKA 06) zenith, SK-II (CRAVENS 08) and SK-III (ABE 11) day/night spectra, and Borexino (BELLINI 10A) spectra. AHARMIM 13 also reported a result combining global solar and KamLAND data, which is $\sin^2(2\ \theta_{13}) = (9.1^{+2.9}_{-3.1}) \times 10^{-2}$.

[30] AN 13 uses six identical detectors, with three placed near the reactor cores (flux-weighted baselines of 498 and 555 m) and the remaining three at the far hall (at the flux averaged distance of 1628 m from all six reactor cores) to determine the $\overline{\nu}_e$ interaction rate ratios. Superseded by AN 14.

[31] ABE 12 determines the $\overline{\nu}_e$ interaction rate in a single detector, located 1050 m from the cores of two reactors. A rate and shape analysis is performed. The rate normalization is fixed by the results of the Bugey4 reactor experiment, thus avoiding any dependence on possible very short baseline oscillations. The value of $\Delta m^2_{31} = 2.4 \times 10^{-3}$ eV^2 is used in the analysis. Superseded by ABE 12B.

[32] ABE 12B determines the neutrino mixing angle θ_{13} using a single detector, located 1050 m from the cores of two reactors. This result is based on a spectral shape and rate analysis. The Bugey4 data (DECLAIS 94) is used to constrain the neutrino flux. Superseded by ABE 14A.

[33] AHN 12 uses two identical detectors, placed at flux weighted distances of 408.56 m and 1433.99 m from six reactor cores, to determine the mixing angle θ_{13}. This rate-only analysis excludes the no-oscillation hypothesis at 4.9 standard deviations. The value of $\Delta m^2_{31} = (2.32^{+0.12}_{-0.08}) \times 10^{-3}$ eV^2 was assumed in the analysis. Superseded by CHOI 16.

[34] AN 12 uses six identical detectors with three placed near the reactor cores (flux-weighted baselines of 470 m and 576 m) and the remaining three at the far hall (at the flux averaged distance of 1648 m from all six reactor cores) to determine the mixing angle θ_{13} using the $\overline{\nu}_e$ observed interaction rate ratios. This rate-only analysis excludes the no-oscillation hypothesis at 5.2 standard deviations. The value of $\Delta m^2_{31} = (2.32^{+0.12}_{-0.08}) \times 10^{-3}$ eV^2 was assumed in the analysis. Superseded by AN 13.

[35] ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{32} fixed to 2.4×10^{-3} eV^2, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, GALLEX/GNO, SAGE, and KamLAND data. This result implies an upper bound of $\sin^2\theta_{13} < 0.059$ (95% CL) or $\sin^2 2\theta_{13} < 0.22$ (95% CL). The normal neutrino mass ordering and CPT invariance are assumed.

[36] ABE 11 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{32} fixed to 2.4×10^{-3} eV^2, using solar neutrino data including Super-Kamiokande, SNO, Borexino (ARPESELLA 08A), Homestake, and GALLEX/GNO data. The normal neutrino mass ordering is assumed.

[37] The quoted limit is for $\Delta m^2_{32} = 2.4 \times 10^{-3}$ eV^2, $\theta_{23} = \pi/2$, $\delta = 0$, and the normal mass ordering. For other values of δ, the 68% region spans from 0.03 to 0.25, and the 90% region from 0.02 to 0.32.

[38] The quoted limit is for $\Delta m^2_{32} = 2.4 \times 10^{-3}$ eV^2, $\theta_{23} = \pi/2$, $\delta = 0$, and the inverted mass ordering. For other values of δ, the 68% region spans from 0.04 to 0.30, and the 90% region from 0.02 to 0.39.

[39] The quoted limit is for $\Delta m^2_{32} = 2.32 \times 10^{-3}$ eV^2, $\theta_{23} = \pi/2$, $\delta = 0$, and the normal mass ordering. For other values of δ, the 68% region spans from 0.02 to 0.12, and the 90% region from 0 to 0.16.

[40] The quoted limit is for $\Delta m^2_{32} = 2.32 \times 10^{-3}$ eV^2, $\theta_{23} = \pi/2$, $\delta = 0$, and the inverted mass ordering. For other values of δ, the 68% region spans from 0.02 to 0.16, and the 90% region from 0 to 0.21.

[41] FOGLI 11 obtained this result from an analysis using the atmospheric, accelerator long baseline, CHOOZ, solar, and KamLAND data. Recently, MUELLER 11 suggested an average increase of about 3.5% in normalization of the reactor $\overline{\nu}_e$ fluxess, and using these fluxes, the fitted result becomes 0.10 ± 0.03.

[42] GANDO 11 report $\sin^2\theta_{13} = 0.020 \pm 0.016$. This result was obtained with three-neutrino fit using the KamLAND + solar data.

[43] GANDO 11 report $\sin^2\theta_{13} = 0.032 \pm 0.037$. This result was obtained with three-neutrino fit using the KamLAND data only.

[44] This result corresponds to the limit of <0.12 at 90% CL for $\Delta m^2_{32} = 2.43 \times 10^{-3}$ eV^2, $\theta_{23} = \pi/2$, and $\delta = 0$. For other values of δ, the 90% CL region spans from 0 to 0.16.

[45] This result corresponds to the limit of <0.20 at 90% CL for $\Delta m^2_{32} = 2.43 \times 10^{-3}$ eV^2, $\theta_{23} = \pi/2$, and $\delta = 0$. For other values of δ, the 90% CL region spans from 0 to 0.21.

[46] AHARMIM 10 global solar neutrino data include SNO's low-energy-threshold analysis survival probability day/night curves, SNO Phase III integral rates (AHARMIM 08), Cl (CLEVELAND 98), SAGE (ABDURASHITOV 09), Gallex/GNO (HAMPEL 99, ALTMANN 05), Borexino (ARPESELLA 08A), SK-I zenith (HOSAKA 06), and SK-II day/night spectra (CRAVENS 08).

[47] AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{31} fixed to 2.3×10^{-3} eV^2, using global solar neutrino data and KamLAND data (ABE 08A). *CPT* invariance is assumed. This result implies an upper bound of $\sin^2\theta_{13} < 0.057$ (95% CL) or $\sin^2 2\theta_{13} < 0.22$ (95% CL).

[48] AHARMIM 10 obtained this result by a three-neutrino oscillation analysis with the value of Δm^2_{31} fixed to 2.3×10^{-3} eV^2, using global solar neutrino data.

[49] WENDELL 10 obtained this result by a three-neutrino oscillation analysis with one mass scale dominance ($\Delta m^2_{21} = 0$) using the Super-Kamiokande-I+II+III atmospheric neutrino data, and updates the HOSAKA 06A result.

[50] The quoted limit is for $\Delta m^2_{32} = 2.43 \times 10^{-3}$ eV^2, $\theta_{23} = \pi/2$, and $\delta = 0$. For other values of δ, the 68% CL region spans from 0.02 to 0.26.

[51] The quoted limit is for $\Delta m^2_{32} = 2.43 \times 10^{-3}$ eV^2, $\theta_{23} = \pi/2$, and $\delta = 0$. For other values of δ, the 68% CL region spans from 0.04 to 0.34.

[52] FOGLI 08 obtained this result from a global analysis of all neutrino oscillation data, that is, solar + KamLAND + atmospheric + accelerator long baseline + CHOOZ.

[53] FOGLI 08 obtained this result from an analysis using the solar and KamLAND neutrino oscillation data.

[54] FOGLI 08 obtained this result from an analysis using the atmospheric, accelerator long baseline, and CHOOZ neutrino oscillation data.

[55] YAMAMOTO 06 searched for $\nu_\mu \to \nu_e$ appearance. Assumes $2\ \sin^2(2\theta_{\mu e}) = \sin^2(2\theta_{13})$. The quoted limit is for $\Delta m^2_{32} = 1.9 \times 10^{-3}$ eV^2. That value of Δm^2_{32} is the one-σ low value for AHN 06A. For the AHN 06A best fit value of 2.8×10^{-3} eV^2, the $\sin^2(2\theta_{13})$ limit is < 0.26. Supersedes AHN 04.

[56] AHN 04 searched for $\nu_\mu \to \nu_e$ appearance. Assuming $2\ \sin^2(2\ \theta_{\mu_e}) = \sin^2(2\ \theta_{13})$, a limit on $\sin^2(2\ \theta_{\mu_e})$ is converted to a limit on $\sin^2(2\ \theta_{13})$.The quoted limit is for $\Delta m^2_{32} = 1.9 \times 10^{-3}$ eV^2. That value of Δm^2_{32} is the one-σ low value for ALIU 05. For the ALIU 05 best fit value of 2.8×10^{-3} eV^2, the $\sin^2(2\ \theta_{13})$ limit is < 0.30.

[57] The quoted limit is for $\Delta m^2_{32} = 1.9 \times 10^{-3}$ eV^2. That value of Δm^2_{32} is the 1-σ low value for ALIU 05. For the ALIU 05 best fit value of 2.8×10^{-3} eV^2, the $\sin^2 2\ \theta_{13}$ limit is < 0.19. In this range, the θ_{13} limit is larger for lower values of Δm^2_{32}, and smaller for higher values of Δm^2_{32}.

[58] The quoted limit is for $\Delta m^2_{32} = 1.9 \times 10^{-3}$ eV^2. That value of Δm^2_{32} is the 1-σ low value for ALIU 05. For the ALIU 05 best fit value of 2.8×10^{-3} eV^2, the $\sin^2 2\ \theta_{13}$ limit is < 0.23.

[59] The quoted limit is for $\Delta m^2_{32} = 2.43 \times 10^{-3}$ eV^2. That value of Δm^2_{32} is the central value for ADAMSON 08. For the ADAMSON 08 1-σ low value of 2.30×10^{-3} eV^2,

the $\sin^2 2\,\theta_{13}$ limit is < 0.16. See also APOLLONIO 03 for a detailed description of the experiment.

CP violating phase

δ, *CP* violating phase

Measurements of δ come from atmospheric and accelarator experiments looking at ν_e appearance. We encode values between 0 and 2π, though it is equivalent to use $-\pi$ to π.

[1] ABE 23F results are based on data collected between 2010 and 2020 in (anti)neutrino mode and include a neutrino beam exposure of 1.97×10^{21} (1.63×10^{21}) protons on target. For inverted mass ordering, the quoted result is $1.54^{+0.18}_{-0.19}$ π rad. Supersedes ABE 20F.

[2] ACERO 22 uses data from Jun 29, 2016 to Feb 26, 2019 (12.5×10^{20} POT) and Feb 6, 2014 to Mar 20, 2020 (13.6×10^{20} POT). Results for normal and inverted mass ordering, and θ_{23} octant I and II are presented. Supersedes ACERO 19.

[3] For the octant I (lower octant), the 68% CL allowed region is discontinuous, and all delta values are allowed at 90% CL.

[4] ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the three parameters, Δm^2_{32}, $\sin^2\theta_{23}$, and δ, while the solar parameters and $\sin^2\theta_{23}$ are fixed to $\Delta m^2_{21} = (7.53 \pm 0.18)\times10^{-5}$ eV^2, $\sin^2\theta_{12} = 0.304 \pm 0.014$, and $\sin^2\theta_{13} = 0.0219 \pm 0.0012$.

[5] The inverted mass ordering is rejected at 1.0 σ. The quoted error bars are based on the local best-fit point.

[6] SALAS 21 reports results of a global fit to neutrino oscillation data available at the time of the Neutrino 2020 conference.

[7] ABE 20F results are based on data collected between 2009 and 2018 in (anti)neutrino mode and include a neutrino beam exposure of 1.49×10^{21} (1.64×10^{21}) protons on target. For inverted mass ordering, the quoted result is $1.56^{+0.15}_{-0.17}$ π rad. Supersedes ABE 18G.

[8] ESTEBAN 20A reports results of a global fit to neutrino oscillation data available at the time of the Neutrino 2020 conference.

[9] ACERO 19 is based on a sample size of 1.33×10^{20} protons on target with combined antineutrino and neutrino data. Superseded by ACERO 22.

[10] ABE 18B uses 328 kton-years of Super-Kamiokande I-IV atmospheric neutrino data to obtain this result. The fit is performed over the four parameters, Δm^2_{32}, $\sin^2\theta_{23}$, $\sin^2\theta_{13}$, and δ, while the solar parameters are fixed to $\Delta m^2_{21} = (7.53 \pm 0.18)\times10^{-5}$ eV^2 and $\sin^2\theta_{12} = 0.304 \pm 0.014$.

[11] ABE 18G confidence intervals are marginalized over both mass orderings. Normal order preferred with a posterior probability of 87%. The 1-sigma result for normal mass ordering used in the average was provided by the experiment via private communications. Supersedes ABE 17F.

[12] ACERO 18 performs a joint fit to the data for ν_μ disappearance and ν_e appearance. The overall best fit favors normal mass ordering and θ_{23} in octant II. No 1σ confidence intervals are presented for the inverted mass ordering scenarios. Superseded by ACERO 19.

[13] ABE 17F confidence intervals are obtained using a frequentist analysis including θ_{13} constraint from reactor experiments. Bayesian intervals based on Markov Chain Monte Carlo method are also provided by the authors. Superseded by ABE 18G.

[14] Errors are projections of 68% C.L. curve of δ_{CP} vs. $\sin^2\theta_{23}$.

[15] ADAMSON 16 result is based on a data sample with 2.74×10^{20} protons on target. The likelihood-based analysis observed 6 ν_e events with an expected background of 0.99 ± 0.11 events.

[16] ADAMSON 14 result is based on three-flavor formalism and $\theta_{23} > \pi/4$. Likelihood as a function of δ is also shown for the other three combinations of hierarchy and θ_{23} octants; all values of δ are allowed at 90% C.L.

[17] GONZALEZ-GARCIA 14 result comes from a frequentist global fit. The corresponding Bayesian global fit to the same data results are reported in BERGSTROM 15 as 68% CL intervals of 1.24–1.94 for normal and 1.15–1.77 for inverted mass ordering.

[18] ADAMSON 13A result is based on ν_e appearance in MINOS and the calculated $\sin^2(2\theta_{23}) = 0.957, \theta_{23} > \pi/4$, and normal mass hierarchy. Likelihood as a function of δ is also shown for the other three combinations of hierarchy and θ_{23} octants; all values of δ are allowed at 90% C.L.

(C) Other neutrino mixing results

The LSND collaboration reported in AGUILAR 01 a signal which is consistent with $\overline{\nu}_\mu \to \overline{\nu}_e$ oscillations. In a three neutrino framework, this would be a measurement of θ_{12} and Δm^2_{21}. This does not appear to be consistent with most of the other neutrino data. The following listings include results from $\nu_\mu \to \nu_e$, $\overline{\nu}_\mu \to \overline{\nu}_e$ appearance and ν_μ, $\overline{\nu}_\mu$, ν_e, and $\overline{\nu}_e$ disappearance experiments, and searches for *CPT* violation.

$\Delta(m^2)$ for $\sin^2(2\theta) = 1$ ($\nu_\mu \to \nu_e$)

[1] AGUILAR-AREVALO 21 result is based on a total of 18.75×10^{20} POT in neutrino mode, and 11.27×10^{20} POT in anti-neutrino mode. Best fit at 0.043 eV^2. The allowed region does not extend to large Δm^2. The quoted value is the entire allowed region of Δm^2 at 90% C.L. for all values of $\sin^2(2\theta)$. Supersedes AGUILAR-AREVALO 18C.

[2] AGUILAR-AREVALO 18C result is based on $\nu_\mu \to \nu_e$ appearance of 460.5 ± 99.0 events; The best fit value is $\Delta m^2 = 0.041$ eV^2. Superseded by AGUILAR-AREVALO 21.

[3] AGUILAR-AREVALO 13A result is based on $\nu_\mu \to \nu_e$ appearance of 162.0 ± 47.8 events; marginally compatible with twoneutrino oscillations. The best fit value is $\Delta m^2 = 3.14$ eV^2.

[4] MAHN 12 is a combined spectral fit of MiniBooNE and SciBooNE neutrino data with the range of Δm^2 up to 25 eV^2. The best limit is 0.04 at 7 eV^2.

[5] AGUILAR 01 is the final analysis of the LSND full data set. Search is made for the $\nu_\mu \to \nu_e$ oscillations using ν_μ from π^+ decay in flight by observing beam-on electron events from $\nu_e C \to e^- X$. Present analysis results in $8.1 \pm 12.2 \pm 1.7$ excess events in the $60 < E_e < 200$ MeV energy range, corresponding to oscillation probability of $0.10 \pm 0.16 \pm 0.04\%$. This is consistent, though less significant, with the previous result of ATHANASSOPOULOS 98, which it supersedes. The present analysis uses selection criteria developed for the decay at rest region, and is less effective in removing the background above 60 MeV than ATHANASSOPOULOS 98.

[6] ATHANASSOPOULOS 98 is a search for the $\nu_\mu \to \nu_e$ oscillations using ν_μ from π^+ decay in flight. The 40 observed beam-on electron events are consistent with $\nu_e C \to e^- X$; the expected background is 21.9 ± 2.1. Authors interpret this excess as evidence for an oscillation signal corresponding to oscillations with probability $(0.26 \pm 0.10 \pm 0.05)\%$. Although the significance is only $2.3\,\sigma$, this measurement is an important and consistent cross check of ATHANASSOPOULOS 96 who reported evidence for $\overline{\nu}_\mu \to \overline{\nu}_e$ oscillations from μ^+ decay at rest. See also ATHANASSOPOULOS 98B.

[7] LOVERRE 96 uses the charged-current to neutral-current ratio from the combined CHARM (ALLABY 86) and CDHS (ABRAMOWICZ 86) data from 1986.

$\sin^2(2\theta)$ for "Large" $\Delta(m^2)$ ($\nu_\mu \to \nu_e$)

[1] AGUILAR-AREVALO 21 result is based on a total of 18.75×10^{20} POT in neutrino mode, and 11.27×10^{20} POT in anti-neutrino mode. The best fit value is $\sin^2(2\theta)$=0.807. The allowed region does not extend to large Δm^2. The quoted value is the entire allowed region of $\sin^2(2\theta)$ at 90% C.L. for all values of Δm^2. Supersedes AGUILAR-AREVALO 18C.

[2] AGUILAR-AREVALO 18C result is based on $\nu_\mu \to \nu_e$ appearance of 460.5 ± 99.0 events; The best fit value is $\sin^2(2\theta) = 0.92$. The quoted limit for the two-neutrino mixing angle θ is valid above $\Delta m^2 = 0.59$ eV^2. Superseded by AGUILAR-AREVALO 21.

[3] AGUILAR-AREVALO 13A result is based on $\nu_\mu \to \nu_e$ appearance of 162.0 ± 47.8 events; marginally compatible with two neutrino oscillations. The best fit value is $\sin^2(2\theta) = 0.002$.

[4] ANTONELLO 13 use the ICARUS T600 detector at LNGS and ~ 20 GeV beam of ν_μ from CERN 730 km away to search for an excess of ν_e events. Two events are found with 3.7 ± 0.6 expected from conventional sources. This result excludes some parts of the parameter space expected by LSND. Superseded by ANTONELLO 13A.

[5] Based on four events with a background of 6.4 ± 0.9 from conventional sources with an average energy of 20 GeV and 730 km from the source of ν_μ.

[6] MAHN 12 is a combined fit of MiniBooNE and SciBooNE neutrino data.

[7] The limit is $\sin^2 2\theta < 0.9 \times 10^{-3}$ at $\Delta m^2 = 2$ eV^2. That value of Δm^2 corresponds to the smallest mixing angle consistent with the reported signal from LSND in AGUILAR 01.

[8] The limit becomes $\sin^2 2\theta < 0.15$ at $\Delta m^2 = 2.8 \times 10^{-3}$ eV^2, the bets-fit value of the ν_μ disappearance analysis in K2K.

[9] AGUILAR 01 is the final analysis of the LSND full data set of the search for the $\nu_\mu \to \nu_e$ oscillations. See footnote in preceding table for further details.

[10] ATHANASSOPOULOS 98 report $(0.26 \pm 0.10 \pm 0.05)\%$ for the oscillation probability; the value of $\sin^2 2\theta$ for large Δm^2 is deduced from this probability. See footnote in preceding table for further details, and see the paper for a plot showing allowed regions. If effect is due to oscillation, it is most likely to be intermediate $\sin^2 2\theta$ and Δm^2. See also ATHANASSOPOULOS 98B.

[11] LOVERRE 96 uses the charged-current to neutral-current ratio from the combined CHARM (ALLABY 86) and CDHS (ABRAMOWICZ 86) data from 1986.

[12] VILAIN 94C limit derived by combining the ν_μ and $\overline{\nu}_\mu$ data assuming *CP* conservation.

$\Delta(m^2)$ for $\sin^2(2\theta) = 1$ ($\overline{\nu}_\mu \to \overline{\nu}_e$)

[1] Based on $\overline{\nu}_\mu \to \overline{\nu}_e$ appearance of 78.4 ± 28.5 events. The best fit values are $\Delta m^2 = 0.043$ eV^2 and $\sin^2 2\theta = 0.88$.

[2] CHENG 12 is a combined fit of MiniBooNE and SciBooNE antineutrino data.

[3] This value is for a two neutrino oscillation analysis for excess antineutrino events with $E_\nu > 475$ MeV. The best fit is at 0.07. The allowed region is consistent with LSND reported by AGUILAR 01. Supercedes AGUILAR-AREVALO 09B.

[4] This value is for a two neutrino oscillation analysis for excess antineutrino events with $E_\nu > 200$ MeV with subtraction of the expected 12 events low energy excess seen in the neutrino component of the beam. The best fit value is 0.007 for $\Delta(m^2) = 4.4$ eV^2.

[5] ARMBRUSTER 02 is the final analysis of the KARMEN 2 data for 17.7 m distance from the ISIS stopped pion and muon neutrino source. It is a search for $\overline{\nu}_e$, detected by the inverse β-decay reaction on protons and ^{12}C. 15 candidate events are observed, and 15.8 ± 0.5 background events are expected, hence no oscillation signal is detected. The results exclude large regions of the parameter area favored by the LSND experiment.

[6] AGUILAR 01 is the final analysis of the LSND full data set. It is a search for $\overline{\nu}_e$ 30 m from LAMPF beam stop. Neutrinos originate mainly for π^+ decay at rest. $\overline{\nu}_e$ are detected through $\overline{\nu}_e p \to e^+ n$ ($20 < E_{e^+} < 60$ MeV) in delayed coincidence with $np \to d\gamma$. Authors observe $87.9 \pm 22.4 \pm 6.0$ total excess events. The observation is attributed to $\overline{\nu}_\mu \to \overline{\nu}_e$ oscillations with the oscillation probability of $0.264 \pm 0.067 \pm 0.045\%$, consistent with the previously published result. Taking into account all constraints, the most favored allowed region of oscillation parameters is a band of $\Delta(m^2)$ from 0.2–2.0 eV^2. Supersedes ATHANASSOPOULOS 95, ATHANASSOPOULOS 96, and ATHANASSOPOULOS 98.

[7] ATHANASSOPOULOS 96 is a search for $\overline{\nu}_e$ 30 m from LAMPF beam stop. Neutrinos originate mainly from π^+ decay at rest. $\overline{\nu}_e$ could come from either $\overline{\nu}_\mu \to \overline{\nu}_e$ or $\nu_e \to \overline{\nu}_e$; our entry assumes the first interpretation. They are detected through $\overline{\nu}_e p \to e^+ n$ (20 MeV $< E_{e^+} <$60 MeV) in delayed coincidence with $np \to d\gamma$. Authors observe $51 \pm 20 \pm 8$ total excess events over an estimated background 12.5 ± 2.9. ATHANASSOPOULOS 96B is a shorter version of this paper.

[8] ATHANASSOPOULOS 95 error corresponds to the 1.6σ band in the plot. The expected background is 2.7 ± 0.4 events. Corresponds to an oscillation probability of $(0.34^{+0.20}_{-0.18} \pm 0.07)\%$. For a different interpretation, see HILL 95. Replaced by ATHANASSOPOULOS 96.

[9] HILL 95 is a report by one member of the LSND Collaboration, reporting a different conclusion from the analysis of the data of this experiment (see ATHANASSOPOULOS 95). Contrary to the rest of the LSND Collaboration, Hill finds no evidence for the neutrino oscillation $\overline{\nu}_\mu \to \overline{\nu}_e$ and obtains only upper limits.

[10] FREEDMAN 93 is a search at LAMPF for $\overline{\nu}_e$ generated from any of the three neutrino types ν_μ, $\overline{\nu}_\mu$, and ν_e which come from the beam stop. The $\overline{\nu}_e$'s would be detected by the reaction $\overline{\nu}_e p \to e^+ n$. FREEDMAN 93 replaces DURKIN 88.

$\sin^2(2\theta)$ for "Large" $\Delta(m^2)$ ($\overline{\nu}_\mu \to \overline{\nu}_e$)

[1] ANTONELLO 13A obtained the limit by assuming $\overline{\nu}_\mu \to \overline{\nu}_e$ oscillation from the $\sim 2\%$ of $\overline{\nu}_\mu$ evnets contamination in the CNGS beam.

[2] CHENG 12 is a combined fit of MiniBooNE and SciBooNE antineutrino data.

[3] This value is for a two neutrino oscillation analysis for excess antineutrino events with $E_\nu > 475$ MeV. At 90% CL there is no solution at high $\Delta(m^2)$. The best fit is at maximal mixing. The allowed region is consistent with LSND reported by AGUILAR 01. Supercedes AGUILAR-AREVALO 09B.

[4] This value is for a two neutrino oscillation analysis for excess antineutrino events with $E_\nu > 200$ MeV with subtraction of the expected 12 events low energy excess seen in the neutrino component of the beam. At 90% CL there is no solution at high $\Delta(m^2)$. The best fit value is 0.007 for $\Delta(m^2) = 4.4$ eV^2.

[5] This result is inconclusive with respect to small amplitude mixing suggested by LSND.

[6] ARMBRUSTER 02 is the final analysis of the KARMEN 2 data. See footnote in the preceding table for further details, and the paper for the exclusion plot.

[7] AGUILAR 01 is the final analysis of the LSND full data set. The deduced oscillation probability is $0.264 \pm 0.067 \pm 0.045\%$; the value of $\sin^2 2\theta$ for large $\Delta(m^2)$ is twice this probability (although these values are excluded by other constraints). See footnote in preceding table for further details, and the paper for a plot showing allowed regions. Supersedes ATHANASSOPOULOS 95, ATHANASSOPOULOS 96, and ATHANASSOPOULOS 98.

[8] ATHANASSOPOULOS 96 reports $(0.31 \pm 0.12 \pm 0.05)\%$ for the oscillation probability; the value of $\sin^2 2\theta$ for large $\Delta(m^2)$ should be twice this probability. See footnote in preceding table for further details, and see the paper for a plot showing allowed regions.

[9] ATHANASSOPOULOS 95 error corresponds to the 1.6σ band in the plot. The expected background is 2.7 ± 0.4 events. Corresponds to an oscillation probability of $(0.34^{+0.20}_{-0.18} \pm 0.07)\%$. For a different interpretation, see HILL 95. Replaced by ATHANASSOPOULOS 96.

[10] HILL 95 is a report by one member of the LSND Collaboration, reporting a different conclusion from the analysis of the data of this experiment (see ATHANASSOPOULOS 95). Contrary to the rest of the LSND Collaboration, Hill finds no evidence for the neutrino oscillation $\overline{\nu}_\mu \rightarrow \overline{\nu}_e$ and obtains only upper limits.

Sterile neutrino limits

$\Delta(m^2)$ for $\sin^2(2\theta) = 1$ ($\nu_\mu \rightarrow \nu_s$)

ν_s means ν_τ or any sterile (noninteracting) ν.

VALUE (10^{-5} eV^2)	CL%	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •					
<3000 (or <550)	90	[1] OYAMA	89	KAMI	Water Cherenkov
< 4.2 or > 54.	90	BIONTA	88	IMB	Flux has ν_μ, $\overline{\nu}_\mu$, ν_e, and $\overline{\nu}_e$

[1] OYAMA 89 gives a range of limits, depending on assumptions in their analysis. They argue that the region $\Delta(m^2) = (100\text{–}1000) \times 10^{-5}$ eV^2 is not ruled out by any data for large mixing.

[1] AKER 23 assume a 3+1 neutrino mixing model, use low-rate commissioning data of the KATRIN tritium β decay experiment to place a limit on $\sin^2(\theta_{14})$ for a admixture sterile neutrino mass m_4 of $\sim$ 300 eV.

[2] ALMAZAN 23 use inverse beta decay data collected by the STEREO experiment, placed 9 to 11 m from the ILL research reactor, to search for $\overline{\nu}_e \rightarrow \overline{\nu}_s$ oscillations. The ILL research reactor uses highly enriched ^{235}U fuel. No indication of the oscillation to sterile neutrinos is found, the stated limit on $\sin^2(2\theta_{14})$ correspond to $\Delta m^2_{41} \sim 1$ eV^2 where the exclusion is maximal. Supersedes ALMAZAN 18.

[3] AKER 22A uses the first two science runs of the KATRIN tritium β decay neutrino mass experiment to search for an admixture of sterile neutrinos. No evidence is found for a spectral anomaly, indicating such admixture. The resulting limit is on $\sin^2(2\theta_{14})$ for sterile neutrino masses $m_4 < 40$ eV. It is most restrictive at $\Delta m^2_{41} \sim 400$ eV^2. A 3+1 model is assumed.

[4] ATIF 22 report results from the combined analysis of the RENO (419 m) and NEOS (24 m) experiments data, collected at the Hanbit Nuclear Power Plant. Results, in terms of $\sin^2(2\theta_{14})$, constrain for $\overline{\nu}_e \rightarrow \overline{\nu}_s$ oscillations. The authors report both excluded and allowed parameter combinations. The exclusion result reported here is based on the Feldman-Cousins method and for $\Delta m^2_{41} \simeq 0.55$ eV^2. Part of the allowed area is excluded by the STEREO and PROSPECT experiments.

[5] BARINOV 22A report an event deficit observed using the segmented Baksan Ga neutrino detector, exposed to a 3.4 MCi ^{51}Cr source. Equal suppression factors are observed for the inner and outer segments. The deficit is interpreted as evidence for oscillations to sterile neutrinos. The result is in terms of $\sin^2(2\theta_{14})$, for a best fit of $\Delta m^2_{41} = 3.3\ ^{+\infty}_{-2.3}$ eV^2. Some, but not all, of the allowed neutrino parameter space conflicts with other experiments.

[6] ANDRIAMIRADO 21 reports a search for $\overline{\nu}_e \rightarrow \overline{\nu}_s$ oscillations at the HFIR research reactor, at baselines from 6.7 to 9.2 m. The reactor has a ^{235}U core. 4 tons of ^{6}Li-doped liquid scintillator are used in a segmented detector. Oscillations into sterile neutrinos are disfavored. The stated limit for $\sin^2(2\theta_{14})$ is for $\Delta m^2_{41} \sim 2$ eV^2 where the sensitivity is maximal.

[7] SEREBROV 21 searches for $\overline{\nu}_e \rightarrow \overline{\nu}_s$ oscillations with a moveable detector with baseline 6–12 m from the SM-3 research reactor with highly enriched ^{235}U fuel. Analyzing the L/E dependence a χ^2 minimum is found at $\Delta m^2_{41} = 7.3 \pm 0.13 \pm 1.16$ eV^2 and $\sin^2(2\theta_{14}) = 0.36 \pm 0.12$. The quoted limit of 0.005 for $\sin^2(2\theta_{14})$ corresponds to $\Delta m^2_{41} \sim 2$ eV^2. This is the result from 720 days of reactor ON and 860 days of reactor OFF measurements. The significance of the χ^2 minimum is 2.9 σ. Supersedes SEREBROV 20, SEREBROV 19 and SEREBROV 18A.

[8] SKROBOVA 20 searches for $\overline{\nu}_e - \overline{\nu}_s$ oscillations using the DANSS detector at 10.7, 11.2, and 12.7 m from the 3.1 GW_{th} power reactor. The DANSS detector is highly segmented and moveable; the positions are changed usually 3 times a week. The analysis is based on the ratio of the events at top and bottom position; the middle position is used for checks of consistency. No evidence for sterile neutrinos is found. The quoted limit 0.008, the smallest excluded $\sin^2(2\theta_{14})$, corresponds to $\Delta m^2_{41} \sim 1.0$ eV^2. Supersedes ALEKSEEV 18.

[9] ALEKSEEV 18 searches for $\overline{\nu}_e \rightarrow \overline{\nu}_s$ oscillations using the DANSS detector at 10.7, 11.2, and 12.7 m from the 3.1 GW_{th} power reactor. The DANSS detector is highly segmented and moveable; the positions are changed usually 3 times a week. The analysis is based on the ratio of the events at top and bottom position; the middle position is used for checks of consistency. The best fit point is at $\Delta m^2_{41} = 1.4$ eV^2 and $\sin^2(2\theta_{14}) = 0.05$ with $\Delta\chi^2 = 13.1$ (statistical errors only) compared to the fit with 3 active neutrinos only. The quoted limit of 0.01 for $\sin^2(2\theta_{14})$ corresponds to $\Delta m^2_{41} \sim 1.0$ eV^2. Superseded by SKROBOVA 20.

[10] ALMAZAN 18 searches for the $\overline{\nu}_e \rightarrow \overline{\nu}_s$ oscillations with baseline from 9.4 to 11.1 m from the ILL research reactor with highly enriched ^{235}U fuel. The STEREO detector consists of six separated cells with Gd loaded scintillator, with 15 m water equivalent overburden. The detected rate is 396.3 ± 4.7 $\overline{\nu}_e$/day with signal to background ratio of about 0.9. The reported results corresponds to 66 days of reactor-on. The analysis uses the relative rates normalized to the cell number 1. No indication of the oscillation to the sterile neutrinos is found, the stated limit on $\sin^2(2\theta_{14})$ correspond to $\Delta m^2_{41} \sim 3.5$ eV^2 where the exclusion is maximal. Superseded by ALMAZAN 23.

[11] ASHENFELTER 18 searches for the $\overline{\nu}_e \rightarrow \overline{\nu}_s$ oscillations at baseline from 6.7 to 9.2 m from the 85 MW research reactor with pure ^{235}U core. The segmented 4 ton ^{6}Li-doped liquid scintillator is operated with about 1 m water equivalent overburden and recorded 25461 ± 283 IBD events. No indication of oscillations into sterile neutrinos was observed. The stated limit for $\sin^2(2\theta_{14})$ is for $\Delta m^2_{41} \sim 2$ eV^2 where the sensitivity is maximal.

[12] AARTSEN 17B uses three years of upward-going atmospheric neutrino data in the energy range of 10-60 GeV to constrain their disappearance into light sterile neutrinos. The reported limit $\sin^2\theta_{24} < 0.11$ at 90% C.L. is for $\Delta m^2_{41} = 1.0$ eV^2. We convert the result to $\sin^2 2\theta_{24}$ for the listing. AARTSEN 17B also reports $\cos^2\theta_{24} \cdot \sin^2\theta_{34} < 0.15$ at 90% C.L. for $\Delta m^2_{41} = 1.0$ eV^2.

[13] ABDURASHITOV 17 use the Troitsk nu-mass experiment to search for sterile neutrinos with mass 0.1 - 2 keV. We convert the reported limit from U^2_{e4} <0.002 to $\sin^2 2\theta_{14}$ <0.008 assume $U_{e4} \sim \sin\theta_{14}$. The stated limit corresponds to the smallest U^2_{e4}. The exclusion curve begins at U^2_{e4} of 0.02 for $m_4 = 0.1$ keV.

[14] KO 17 reports on short baseline reactor oscillation search ($\overline{\nu}_e \rightarrow \overline{\nu}_s$), motivated be the so-called "reactor antineutrino anomaly". The experiment is conducted at 23.7 m from the core of unit 5 of the Hanbit Nuclear Power Complex in Korea. the reported limited on $\sin^2(2\theta_{41})$ for sterile neutrinos was determined using the reactor antineutrino spectrum determined by the Daya Bay experiment for Δm^2_{14} around 0.55 eV^2 where the sensitivity is maximal. A fraction of the parameter space derived from the "reactor antineutrino anomaly" is excluded by this work. Compared to reactor models an event excess is observed at about 5 MeV, in agreement with other experiments.

[15] AARTSEN 16 use one year of upward-going atmospheric muon neutrino data in the energy range of 320 GeV to 20 TeV to constrain their disappearance into light sterile neutrinos. Sterile neutrinos are expected to produce distinctive zenith distribution for these energies for $0.01 \leq \Delta m^2 \leq 10$ eV^2. The stated limit is for $\sin^2 2\theta_{24}$ at Δm^2 around 0.3 eV^2.

[16] ADAMSON 16B combine the results of AN 16B, ADAMSON 16C, and Bugey-3 reactor experiments to constrain ν_μ to ν_e mixing through oscillations into light sterile neutrinos. The stated limit for $\sin^2 2\theta_{\mu e}$ is at $|\Delta m^2_{41}| = 1.2$ eV^2.

[17] ADAMSON 16C use the NuMI beam and exposure of 10.56×10^{20} protons on target to search for the oscillation of ν_μ dominated beam into light sterile neutrinos with detectors at 1.04 and 735 km. The reported limit $\sin^2(\theta_{24}) < 0.022$ at 95% C.L. is for $|\Delta m^2_{41}| = 0.5$ eV^2. We convert the result to $\sin^2(2\theta_{24})$ for the listing.

[18] AN 16B utilize 621 days of data to place limits on the $\overline{\nu}_e$ disappearance into a light sterile neutrino. The stated limit corresponds to the smallest $\sin^2(2\theta_{14})$ at $|\Delta m^2_{41}| \sim 3 \times 10^{-2}$ eV^2 (obtained from Figure 3 in AN 16B). The exclusion curve begins at $|\Delta m^2_{41}| \sim 1.5 \times 10^{-4}$ eV^2 and extends to ~ 0.25 eV^2. The analysis assumes $\sin^2(2\theta_{12}) = 0.846 \pm 0.021$, $\Delta m^2_{21} = (7.53 \pm 0.18) \times 10^{-5}$ eV^2, and $|\Delta m^2_{32}| = (2.44 \pm 0.06) \times 10^{-3}$ eV^2.

[19] AMBROSIO 01 tested the pure 2-flavor $\nu_\mu \rightarrow \nu_s$ hypothesis using matter effects which change the shape of the zenith-angle distribution of upward through-going muons. With maximum mixing and Δm^2 around 0.0024 eV^2, the $\nu_\mu \rightarrow \nu_s$ oscillation is disfavored with 99% confidence level with respect to the $\nu_\mu \rightarrow \nu_\tau$ hypothesis.

[20] FUKUDA 00 tested the pure 2-flavor $\nu_\mu \rightarrow \nu_s$ hypothesis using three complementary atmospheric-neutrino data samples. With this hypothesis, zenith-angle distributions are expected to show characteristic behavior due to neutral currents and matter effects. In the Δm^2 and $\sin^2 2\theta$ region preferred by the Super-Kamiokande data, the $\nu_\mu \rightarrow \nu_s$ hypothesis is rejected at the 99% confidence level, while the $\nu_\mu \rightarrow \nu_\tau$ hypothesis consistently fits all of the data sample.

Heavy Neutral Leptons, Searches for

OMITTED FROM SUMMARY TABLE

We define searches for Heavy Neutral Leptons (HNLs) as searches for Dirac or Majorana fermions with sterile neutrino quantum numbers, that are heavy enough to not disrupt the simplest Big Bang Nucleosynthesis bounds and/or unstable on cosmological timescales: Typically HNLs have mass $\sim$ MeV or higher.

Searches for these particles generically set bounds on the mixing between the HNL and the active neutrinos, as parametrized by the extended 3×4 PMNS matrix elements $U_{\ell X}$ (see the "Neutrino mass, mixing and oscillations" review) where $\ell = e$, μ or τ, and we denote the HNL as ν_X. While many measurements may be interpreted to place bounds on various combinations of these matrix elements, we quote below limits only for those cases in which one matrix element is assumed to be much larger than the other two, i.e. $|U_{\ell X}| \gg |U_{\ell' X}|$ for $\ell' \neq \ell$.

Experimental searches make use of various different strategies, including e.g. resonance searches in missing mass decay distributions or specific final states, searches for lepton number violating decays, and trilepton signatures. The resulting bounds on $U_{\ell X}$ are typically dependent on the HNL mass. The quoted limits below are either the best limit near an experimental kinematic threshold, or a characteristic value in the mass range of the experimental sensitivity.

Limits on heavy neutral lepton mixing parameters

Limits on $|U_{ex}|^2$

Quoted limits are either the best limit near the kinematic threshold of the experiment, or a characteristic value in the mass range of the experimental sensitivity

[1] AAD 23AO search for $W\to\nu_X e$, for both Majorana and Dirac HNL scenarios. Also consider scenarios involving multiflavor mixing, with correspondingly weaker limits.

[2] Search for ionization signals in an LArTPC. Assumes the candidate particle is 100% of dark matter.

[3] Reanalysis of BEBC results (cf. COOPER-SARKAR 85) to update searches for $D_s^\pm\to\nu_X e^\pm$ using a corrected formula for the HNL decay probabilities, additional production channels, and an improved fit for the charm meson distributions. Assumes a Majorana HNL.

[4] TUMASYAN 22AD search for $W\to e\nu_X$, $\nu_X\to e\mu\nu_\mu$ and set limits for Dirac and Majorana Heavy Neutral Leptons. The data correspond to an integrated luminosity of 138 fb^{-1}.

[5] Search in electron capture decay $^7\mathrm{Be}\to{}^7\mathrm{Li}\nu_X$. Kinematic threshold is $\sim$ 850 keV.

[6] Search for $K^+\to e^+\nu_X$. Assumes lifetime of $\nu_X > 50$ ns.

[7] Limit from prompt lepton number violating trilepton search.

[8] $K^+\to e^+\nu_X$, with ν_X decay through U_{eX}. ABE 19B also considers bounds on $|U_{\ell X}\,U_{\ell' X}|$ for combinations of lepton flavors in the ν_X decay final state.

[9] Searches for a Majorana Heavy Neutral Lepton producing a π^-e^+ resonance in the same sign dilepton decay $D\to K\pi^-e^+e^+$.

[10] BRYMAN 19 sets best limits $|U_{eX}|^2 < 1\times10^{-4}$–$2\times10^{-7}$ in the mass range $m_{\nu_X}\sim$ 2–55 MeV, respectively, using the precision branching ratio measurement in AGUILAR-AREVALO 15. See also BRYMAN 19A.

[11] Search for $\pi^+\to e^+\nu_X$.

[12] Search for $K^+\to e^+\nu_X$.

[13] PARK 16 quotes an approximate limit $B(B^+\to e^+\nu_X) < 3\times10^{-6}$ in the mass range $m_{\nu_X}\sim$ 0.2–1.4 GeV.

[14] Search for $B^+\to e^+\nu_X$.

[15] Search for prompt ν_X decay signatures.

[16] Search for displaced ν_X decay signatures.

[17] Searches for K or $\pi\to e^+\nu_X$, $\nu_X\to e^+e^-\nu_e$ using a beam dump experiment at the 70 GeV Serpukhov proton synchrotron. BARANOV 93 also considers limits for $|U_{eX}\,U_{\mu X}|$ from K or $\pi\to\mu^+\nu_X$, $\nu_X\to e^+e^-\nu_e$.

[18] $\pi^+\to e^+\nu_X$, with ν_X decay through U_{eX}.

[19] BERNARDI 88 also considers bounds on $|U_{eX}\,U_{\mu X}|$.

[20] $K^+\to e^+\nu_X$, with ν_X decay through U_{eX}.

[21] $D^+\to e^+\nu_X$, with $\nu_X\to e^-\ell^+\nu_\ell$.

[22] $D^+\to e^+\nu_X$, with $\nu_X\to e^-\ell^+\nu_\ell$ or $\nu_X\to e^-\pi^+$.

Limits on $|U_{\mu x}|^2$

Quoted limits are either the best limit near the kinematic threshold of the experiment, or a characteristic value in the mass range of the experimental sensitivity

<1	$\times 10^{-7}$	90	[29] ABRATENKO	20	MBNE	Superseded by ABRATENKO 22A

[1] AAD 23AO search for $W \to \nu_X \mu$, for both Majorana and Dirac HNL scenarios. Also consider scenarios involving multiflavor mixing, with correspondingly weaker limits.

[2] AAD 23CE search for Majorana HNLs via vector boson fusion $W^\pm W^\pm \to \mu^\pm \mu^\pm$. Limits set in a m_{ν_X} mass range from 50 GeV up to 20 TeV, using the Phenomenological Type-I Seesaw model as a benchmark scenario.

[3] TUMASYAN 23AC search for Majorana HNLs via vector boson fusion $W^\pm W^\pm \to \mu^\pm \mu^\pm$. Limits set in a m_{ν_X} mass range from 50 GeV up to 25 TeV.

[4] ABRATENKO 22A search for $K^+ \to \mu^+ \nu_X$, with $\nu_X \to \mu^\mp \pi^\pm$, in the mass range $m_{\nu_X} \sim$ 246–385 MeV. Also considers limits from $\nu_X \to \mu^- \pi^+$ only, for the case of a Dirac HNL.

[5] TUMASYAN 22AD search for $W \to \mu \nu_X$, $\nu_X \to \mu e \nu_e$ and set limits for Dirac and Majorana Heavy Neutral Leptons. The data correspond to an integrated luminosity of 138 fb^{-1}.

[6] Limit from prompt lepton number conserving $W \to \mu \mu j$ search.

[7] Limit from prompt lepton number violating $W \to \mu \mu j$ search .

[8] Search for $K^+ \to \mu^+ \nu_X$.

[9] Assumes a lifetime exceeding 50 ns, and searches over m_{ν_X} range 200–384 MeV.

[10] Search for $B^+ \to \mu^+ \nu_X$ in the mass range $m_{\nu_X} \sim$ 0–1.5 GeV .

[11] Limit from prompt lepton number violating trilepton search.

[12] Limit from displaced lepton violating or conserving trilepton searches.

[13] $K^+ \to \mu^+ \nu_X$, with ν_X decay through $U_{\mu X}$. ABE 19B also considers bounds on $|U_{\ell X}\ U_{\ell' X}|$ for combinations of lepton flavors in the ν_X decay final state.

[14] Limit requires muon kinetic energy > 1.2 MeV.

[15] Search for $\pi^+ \to \mu^+ \nu_X$.

[16] PARK 16 quotes an approximate limit $B(B^+ \to \mu^+ \nu_X) < 3 \times 10^{-6}$ in the mass range $m_{\nu_X} \sim$ 0.2–1.4 GeV.

[17] Search for $B^+ \to \mu^+ \nu_X$.

[18] DAUM 00 quotes a branching ratio bound $B(\pi^+ \to \mu^+ \nu_X) < 6.0 \times 10^{-10}$ at 95% CL.

[19] $K^+ \to \mu^+ \nu_X$, with $\nu_X \to \mu X$.

[20] $D_s \to \mu^+ \nu_X$, with $\nu_X \to \mu X$.

[21] Search for prompt ν_X decay signatures.

[22] Search for displaced ν_X decay signatures.

[23] Search for Heavy Neutral Leptons produced by neutral current muon neutrino interactions, with $\nu_X \to \mu^+ \mu^- \nu_\mu$.

[24] $K^+ \to \mu^+ \nu_X$, with ν_X decay through $U_{\mu X}$ and $m_{\nu_X} < m_\mu + m_\pi$.

[25] BERNARDI 88 also considers bounds on $|U_{eX}\ U_{\mu X}|$.

[26] $K^+ \to \mu^+ \nu_X$, with $\nu_X \to \mu^- \pi^+$.

[27] $D^+ \to \mu^+ \nu_X$, with $\nu_X \to \mu^- \ell^+ \nu_\ell$.

[28] $D^+ \to \mu^+ \nu_X$, with $\nu_X \to \mu^- \ell^+ \nu_\ell$ or $\nu_X \to \mu^- \pi^+$.

[29] $K^+ \to \mu^+ \nu_X$, with $\nu_X \to \mu^- \pi^+$, in the mass range $m_{\nu_X} \sim$ 260–385 MeV. ABRATENKO 20 also considers $\nu_X \to \mu^+ \pi^-$ for the case of a Majorana HNL.

Limits on $|U_{\tau x}|^2$

Quoted limits are either the best limit near the kinematic threshold of the experiment, or a characteristic value in the mass range of the experimental sensitivity

[1] Search for $\tau^\pm \to \pi^\pm \pi^+ \pi^- \nu_X$.

[2] Reanalysis of BEBC results (cf. COOPER-SARKAR 85) to include searches for $D_s^\pm \to \nu_\tau \tau^\pm$, $\tau^\pm \to \nu_X \pi^\pm$, $\nu_X \rho^\pm$, or $\nu_X \nu_\tau \ell^\pm$ via $U_{\tau X}$. Assumes a Majorana HNL.

[3] Search for $\nu_X \to \mu^+ \mu^- \nu$.

[4] Reanalysis of CHARM results (cf. ORLOFF 02) to include searches for $\nu_X \to \nu \ell^+ \ell^-$ decays, and including the production of HNLs from τ decays.

[5] $D_s \to \tau^+ \nu_X$, with ν_X decay via $U_{\tau X}$.

[6] $D_s \to \nu_\tau \tau^+$, $\tau^+ \to \nu_X X$, with ν_X decay via $U_{\tau X}$.

[7] Search for prompt ν_X decay signatures.

[8] Search for displaced ν_X decay signatures. Kinematical suppression of $\nu_X \to \tau X$ at lower masses leads to rapid loosening of the $|U_{\tau X}|$ bound compared to that for $|U_{eX}|$ and $|U_{\mu X}|$.

[9] Search for $\tau \to \pi \nu_X$, $\nu_X \to \pi e$ or $\pi \mu$ in the range 0.2–1.6 GeV. LIVENTSEV 23 reports results for the sum $\Sigma_{\ell=e,\mu,\tau} |U_{\ell X}|^2$ in a model-dependent context, but which may be roughly reinterpreted as a limit $|U_{eX}\ U_{\tau X}|^2 + |U_{\mu X}\ U_{\tau X}|^2 \lesssim 5 \times 10^{-9}$ in either Majorana or Dirac HNL scenarios.

[10] TUMASYAN 22H sets limits on an approximately mass-degenerate vector-like lepton SU(2) doublet coupling to the τ. Some of the reported signal region distributions might be used to set limits for heavy neutral leptons coupled to the τ. The data correspond to an integrated luminosity of 138 fb^{-1}.

Quark Masses

u-QUARK MASS

The u-, d-, and s-quark masses are estimates of so-called "current-quark masses," in a mass- independent subtraction scheme such as $\overline{\text{MS}}$. The ratios m_u/m_d and m_s/m_d are extracted from pion and kaon masses using chiral symmetry. The estimates of d and u masses are not without controversy and remain under active investigation. Within the literature there are even suggestions that the u quark could be essentially massless. The s-quark mass is estimated from SU(3) splittings in hadron masses.

We have normalized the $\overline{\text{MS}}$ masses at a renormalization scale of $\mu = 2$ GeV. Results quoted in the literature at $\mu = 1$ GeV have been rescaled by dividing by 1.35. The values of "Our Evaluation" were determined in part via Figures 2 and 3 in the "Quark masses" review.

[1] DOMINGUEZ 19 determine the quark mass from a QCD finite energy sum rule for the divergence of the axial current.

[2] BAZAVOV 18 determine the quark masses using a lattice computation with staggered fermions and four active quark flavors.

[3] FODOR 16 is a lattice simulation with $n_f = 2 + 1$ dynamical flavors and includes partially quenched QED effects.

[4] CARRASCO 14 is a lattice QCD computation of light quark masses using $2 + 1 + 1$ dynamical quarks, with $m_u = m_d \neq m_s \neq m_c$. The u and d quark masses are obtained separately by using the K meson mass splittings and lattice results for the electromagnetic contributions.

[5] BLUM 10 determines light quark masses using a QCD plus QED lattice computation of the electromagnetic mass splittings of the low-lying hadrons. The lattice simulations use 2+1 dynamical quark flavors.

[6] DAVIES 10 and MCNEILE 10 determine $\overline{m}_c(\mu)/\overline{m}_s(\mu) = 11.85 \pm 0.16$ using a lattice computation with $n_f = 2 + 1$ dynamical fermions of the pseudoscalar meson masses. Mass m_u is obtained from this using the value of m_c from ALLISON 08 or MCNEILE 10 and the BAZAVOV 10 values for the light quark mass ratios, $m_s/\overline{m}$ and m_u/m_d.

[7] AOKI 12 is a lattice computation using $1 + 1 + 1$ dynamical quark flavors.

[8] DURR 11 determine quark mass from a lattice computation of the meson spectrum using $n_f = 2 + 1$ dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed. The individual m_u, m_d values are obtained using the lattice determination of the average mass m_{ud} and of the ratio m_s/m_{ud} and the value of $Q = (m_s^2 - m_{ud}^2)\,/\,(m_d^2 - m_u^2)$ as determined from $\eta \to 3\pi$ decays.

[9] BAZAVOV 10 is a lattice computation using 2+1 dynamical quark flavors.

[10] DOMINGUEZ 09 use QCD finite energy sum rules for the two-point function of the divergence of the axial vector current computed to order α_s^4.

[11] DEANDREA 08 determine $m_u - m_d$ from $\eta \to 3\pi^0$, and combine with the PDG 06 lattice average value of $m_u + m_d = 7.6 \pm 1.6$ to determine m_u and m_d.

[12] BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.

[13] JAMIN 06 determine m_u(2 GeV) by combining the value of m_s obtained from the spectral function for the scalar $K\pi$ form factor with other determinations of the quark mass ratios.

[14] MASON 06 extract light quark masses from a lattice simulation using staggered fermions with an improved action, and three dynamical light quark flavors with degenerate u and d quarks. Perturbative corrections were included at NNLO order. The quark masses m_u and m_d were determined from their $(m_u + m_d)/2$ measurement and AUBIN 04A m_u/m_d value.

[15] NARISON 06 uses sum rules for $e^+e^- \to$ hadrons to order α_s^3 to determine m_s combined with other determinations of the quark mass ratios.

[16] AUBIN 04A employ a partially quenched lattice calculation of the pseudoscalar meson masses.

[1] ALEXANDROU 21 determines the quark mass using a lattice calculation of the meson and baryon masses with a twisted mass fermion action. The simulations are carried out using 2+1+1 dynamical quarks with $m_u = m_d \neq m_s \neq m_c$, including gauge ensembles close to the physical pion point.

[2] BRUNO 20 determines the light quark mass using a lattice calculation with $n_f = 2+1$ flavors of Wilson fermions. The scale has been set from f_π and f_K. The tuning was done using the masses of the lightest (π) and strange (K) pseudoscalar mesons.

[3] DOMINGUEZ 19 determine the quark mass from a QCD finite energy sum rule for the divergence of the axial current.

[4] YUAN 17 determine $\overline{m}$ using QCD sum rules in the isospin $I=0$ scalar channel. At the end of the "Numerical Results" section of YUAN 17 the authors discuss the significance of their larger value of the light quark mass compared to previous determinations.

[5] CARRASCO 14 is a lattice QCD computation of light quark masses using $2+1+1$ dynamical quarks, with $m_u = m_d \neq m_s \neq m_c$. The u and d quark masses are obtained separately by using the K meson mass splittings and lattice results for the electromagnetic contributions.

[6] ARTHUR 13 is a lattice computation using 2+1 dynamical domain wall fermions. Masses at $\mu = 3$ GeV have been converted to $\mu = 2$ GeV using conversion factors given in their paper.

[7] DURR 11 determine quark mass from a lattice computation of the meson spectrum using $n_f = 2+1$ dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed.

[8] BLOSSIER 10 determines quark masses from a computation of the hadron spectrum using n_f=2 dynamical twisted-mass Wilson fermions.

[9] DAVIES 10 and MCNEILE 10 determine $\overline{m}_c(\mu)/\overline{m}_s(\mu) = 11.85 \pm 0.16$ using a lattice computation with $n_f = 2+1$ dynamical fermions of the pseudoscalar meson masses. Mass $\overline{m}$ is obtained from this using the value of m_c from ALLISON 08 or MCNEILE 10 and the BAZAVOV 10 values for the light quark mass ratio, $m_s/\overline{m}$.

[10] AOKI 11A determine quark masses from a lattice computation of the hadron spectrum using $n_f = 2+1$ dynamical flavors of domain wall fermions.

[11] DOMINGUEZ 09 use QCD finite energy sum rules for the two-point function of the divergence of the axial vector current computed to order α_s^4.

[12] ALLTON 08 use a lattice computation of the π, K, and Ω masses with 2+1 dynamical flavors of domain wall quarks, and non-perturbative renormalization.

[13] BLOSSIER 08 use a lattice computation of pseudoscalar meson masses and decay constants with 2 dynamical flavors and non-perturbative renormalization.

[14] DOMINGUEZ-CLARIMON 08B obtain an inequality from sum rules for the scalar two-point correlator.

[15] ISHIKAWA 08 use a lattice computation of the light meson spectrum with 2+1 dynamical flavors of $\mathcal{O}(a)$ improved Wilson quarks, and one-loop perturbative renormalization.

[16] NAKAMURA 08 do a lattice computation using quenched domain wall fermions and non-perturbative renormalization.

[17] BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.

[18] GOCKELER 06 use an unquenched lattice computation of the axial Ward Identity with $n_f = 2$ dynamical light quark flavors, and non-perturbative renormalization, to obtain $\overline{m}$(2 GeV) = $4.08 \pm 0.25 \pm 0.19 \pm 0.23$ MeV, where the first error is statistical, the second and third are systematic due to the fit range and force scale uncertainties, respectively. We have combined the systematic errors linearly.

[19] GOCKELER 06A use an unquenched lattice computation of the pseudoscalar meson masses with $n_f = 2$ dynamical light quark flavors, and non-perturbative renormalization.

[20] MASON 06 extract light quark masses from a lattice simulation using staggered fermions with an improved action, and three dynamical light quark flavors with degenerate u and d quarks. Perturbative corrections were included at NNLO order.

[21] NARISON 06 uses sum rules for $e^+e^- \to$ hadrons to order α_s^3 to determine m_s combined with other determinations of the quark mass ratios.

[22] AUBIN 04 perform three flavor dynamical lattice calculation of pseudoscalar meson masses, with one-loop perturbative renormalization constant.

[23] AOKI 03 uses quenched lattice simulation of the meson and baryon masses with degenerate light quarks. The extrapolations are done using quenched chiral perturbation theory.

[24] The errors given in AOKI 03B were $^{+0.046}_{-0.069}$. We changed them to ±0.3 for calculating the overall best values. AOKI 03B uses lattice simulation of the meson and baryon masses with two dynamical light quarks. Simulations are performed using the $\mathcal{O}(a)$ improved Wilson action.

[25] BECIREVIC 03 perform quenched lattice computation using the vector and axial Ward identities. Uses $\mathcal{O}(a)$ improved Wilson action and nonperturbative renormalization.

[26] CHIU 03 determines quark masses from the pion and kaon masses using a lattice simulation with a chiral fermion action in quenched approximation.

[1] FODOR 16 is a lattice simulation with $n_f = 2 + 1$ dynamical flavors and includes partially quenched QED effects.

[2] BASAK 15 is a lattice computation using 2+1 dynamical quark flavors.

[3] CARRASCO 14 is a lattice QCD computation of light quark masses using $2 + 1 + 1$ dynamical quarks, with $m_u = m_d \neq m_s \neq m_c$. The u and d quark masses are obtained separately by using the K meson mass splittings and lattice results for the electromagnetic contributions.

[4] BAZAVOV 10 is a lattice computation using 2+1 dynamical quark flavors.

[5] BLUM 10 is a lattice computation using 2+1 dynamical quark flavors.

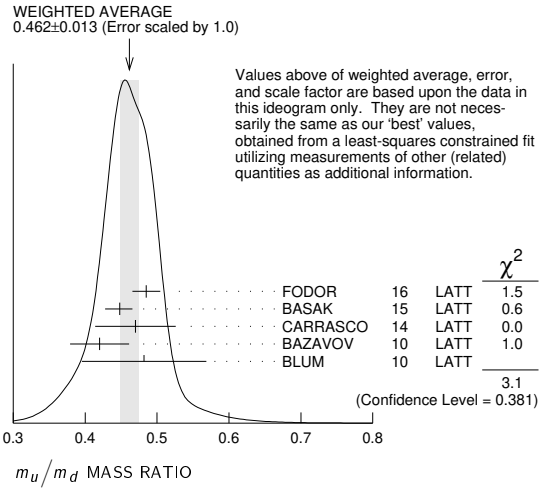
[6] AOKI 12 is a lattice computation using $1 + 1 + 1$ dynamical quark flavors.

[7] BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.

[8] AUBIN 04A perform three flavor dynamical lattice calculation of pseudoscalar meson masses, with continuum estimate of electromagnetic effects in the kaon masses.

[9] NELSON 03 computes coefficients in the order p^4 chiral Lagrangian using a lattice calculation with three dynamical flavors. The ratio m_u/m_d is obtained by combining this with the chiral perturbation theory computation of the meson masses to order p^4.

[10] LEUTWYLER 96 uses a combined fit to $\eta \to 3\pi$ and $\psi' \to J/\psi\,(\pi,\eta)$ decay rates, and the electromagnetic mass differences of the π and K.



s-QUARK MASS

See the comment for the u quark above.

We have normalized the $\overline{\text{MS}}$ masses at a renormalization scale of $\mu = 2$ GeV. Results quoted in the literature at $\mu = 1$ GeV have been rescaled by dividing by 1.35.

[1] ALEXANDROU 21 determines the quark mass using a lattice calculation of the meson and baryon masses with a twisted mass fermion action. The simulations are carried out using 2+1+1 dynamical quarks with $m_u = m_d \neq m_s \neq m_c$, including gauge ensembles close to the physical pion point.

[2] BRUNO 20 determines the light quark mass using a lattice calculation with $n_f = 2+1$ flavors of Wilson fermions. The scale has been set from f_π and f_K. The tuning was done using the masses of the lightest (π) and strange (K) pseudoscalar mesons.

[3] BAZAVOV 18 determine the quark masses using a lattice computation with staggered fermions and four active quark flavors.

[4] LYTLE 18 combined with CHAKRABORTY 2015 determine $\overline{m}_s(3\text{ GeV}) = 84.78 \pm 0.65$ MeV from a lattice simulation with $n_f = 2+1+1$ flavors. They also determine the quoted value $\overline{m}_s(2\text{ GeV})$ for $n_f = 4$ dynamical flavors.

[5] ANANTHANARAYAN 16 determine $\overline{m}_s(2\text{ GeV}) = 106.70 \pm 9.36$ MeV and 74.47 ± 7.77 MeV from fits to ALEPH and OPAL τ decay data, respectively. We have used the weighted average of the two.

[6] CARRASCO 14 is a lattice QCD computation of light quark masses using $2 + 1 + 1$ dynamical quarks, with $m_u = m_d \neq m_s \neq m_c$. The u and d quark masses are obtained separately by using the K meson mass splittings and lattice results for the electromagnetic contributions.

[7] ARTHUR 13 is a lattice computation using 2+1 dynamical domain wall fermions. Masses at $\mu = 3$ GeV have been converted to $\mu = 2$ GeV using conversion factors given in their paper.

[8] BODENSTEIN 13 determines m_s from QCD finite energy sum rules, and the perturbative computation of the pseudoscalar correlator to five-loop order.

[9] DURR 11 determine quark mass from a lattice computation of the meson spectrum using $n_f = 2 + 1$ dynamical flavors. The lattice simulations were done at the physical quark mass, so that extrapolation in the quark mass was not needed.

[10] CHAKRABORTY 15 is a lattice QCD computation that determines m_c and m_c/m_s using pseudoscalar mesons masses tuned on gluon field configurations with 2+1+1 dynamical flavors of HISQ quarks with u/d masses down to the physical value.

[11] FRITZSCH 12 determine m_s using a lattice computation with $n_f = 2$ dynamical flavors.

[12] AOKI 11A determine quark masses from a lattice computation of the hadron spectrum using $n_f = 2 + 1$ dynamical flavors of domain wall fermions.

[13] BLOSSIER 10 determines quark masses from a computation of the hadron spectrum using n_f=2 dynamical twisted-mass Wilson fermions.

[14] BLUM 10 determines light quark masses using a QCD plus QED lattice computation of the electromagnetic mass splittings of the low-lying hadrons. The lattice simulations use 2+1 dynamical quark flavors.
[15] DAVIES 10 and MCNEILE 10 determine $\overline{m}_C(\mu)/\overline{m}_S(\mu) = 11.85 \pm 0.16$ using a lattice computation with $n_f = 2 + 1$ dynamical fermions of the pseudoscalar meson masses. Mass m_S is obtained from this using the value of m_C from ALLISON 08 or MCNEILE 10.
[16] ALLTON 08 use a lattice computation of the π, K, and Ω masses with 2+1 dynamical flavors of domain wall quarks, and non-perturbative renormalization.
[17] BLOSSIER 08 use a lattice computation of pseudoscalar meson masses and decay constants with 2 dynamical flavors and non-perturbative renormalization.
[18] DOMINGUEZ 08A make determination from QCD finite energy sum rules for the pseudoscalar two-point function computed to order α_s^4.
[19] ISHIKAWA 08 use a lattice computation of the light meson spectrum with 2+1 dynamical flavors of $\mathcal{O}(a)$ improved Wilson quarks, and one-loop perturbative renormalization.
[20] NAKAMURA 08 do a lattice computation using quenched domain wall fermions and non-perturbative renormalization.
[21] BLUM 07 determine quark masses from the pseudoscalar meson masses using a QED plus QCD lattice computation with two dynamical quark flavors.
[22] CHETYRKIN 06 use QCD sum rules in the pseudoscalar channel to order α_s^4.
[23] GOCKELER 06 use an unquenched lattice computation of the axial Ward Identity with $n_f = 2$ dynamical light quark flavors, and non-perturbative renormalization, to obtain $\overline{m}_s(2\text{ GeV}) = 111 \pm 6 \pm 4 \pm 6$ MeV, where the first error is statistical, the second and third are systematic due to the fit range and force scale uncertainties, respectively. We have combined the systematic errors linearly.
[24] GOCKELER 06A use an unquenched lattice computation of the pseudoscalar meson masses with $n_f = 2$ dynamical light quark flavors, and non-perturbative renormalization.
[25] JAMIN 06 determine $\overline{m}_s(2\text{ GeV})$ from the spectral function for the scalar $K\pi$ form factor.
[26] MASON 06 extract light quark masses from a lattice simulation using staggered fermions with an improved action, and three dynamical light quark flavors with degenerate u and d quarks. Perturbative corrections were included at NNLO order.
[27] NARISON 06 uses sum rules for $e^+e^- \to$ hadrons to order α_s^3.
[28] NARISON 06 obtains the quoted range from positivity of the spectral functions.
[29] BAIKOV 05 determines $\overline{m}_s(M_\tau) = 100^{+5}_{-3}{}^{+17}_{-19}$ from sum rules using the strange spectral function in τ decay. The computations were done to order α_s^3, with an estimate of the α_s^4 terms. We have converted the result to $\mu = 2$ GeV.
[30] GAMIZ 05 determines $\overline{m}_s(2\text{ GeV})$ from sum rules using the strange spectral function in τ decay. The computations were done to order α_s^2, with an estimate of the α_s^3 terms.
[31] GORBUNOV 05 use hadronic tau decays to N3LO, including power corrections.
[32] NARISON 05 determines $\overline{m}_s(2\text{ GeV})$ from sum rules using the strange spectral function in τ decay. The computations were done to order α_s^3.
[33] AUBIN 04 perform three flavor dynamical lattice calculation of pseudoscalar meson masses, with one-loop perturbative renormalization constant.
[34] AOKI 03 uses quenched lattice simulation of the meson and baryon masses with degenerate light quarks. The extrapolations are done using quenched chiral perturbation theory. Determines m_s=113.8 $\pm$ 2.3$^{+5.8}_{-2.9}$ using K mass as input and m_s=142.3 $\pm$ 5.8$^{+22}_{-0}$ using ϕ mass as input. We have performed a weighted average of these values.
[35] AOKI 03B uses lattice simulation of the meson and baryon masses with two dynamical light quarks. Simulations are performed using the $\mathcal{O}(a)$ improved Wilson action.
[36] BECIREVIC 03 perform quenched lattice computation using the vector and axial Ward identities. Uses $\mathcal{O}(a)$ improved Wilson action and nonperturbative renormalization. They also quote $\overline{m}/m_s$=24.3 $\pm$ 0.2 $\pm$ 0.6.
[37] CHIU 03 determines quark masses from the pion and kaon masses using a lattice simulation with a chiral fermion action in quenched approximation.
[38] GAMIZ 03 determines m_S from SU(3) breaking in the τ hadronic width. The value of V_{us} is chosen to satisfy CKM unitarity.
[39] GAMIZ 03 determines m_S from SU(3) breaking in the τ hadronic width. The value of V_{us} is taken from the PDG.

c-QUARK MASS

The c-quark mass corresponds to the "running" mass m_c ($\mu = m_c$) in the $\overline{\text{MS}}$ scheme. We have converted masses in other schemes to the $\overline{\text{MS}}$ scheme using two-loop QCD perturbation theory with $\alpha_s(\mu{=}m_c) = 0.38 \pm 0.03$. The value 1.2730 ± 0.0046 GeV for the $\overline{\text{MS}}$ mass corresponds to 1.67 ± 0.07 GeV for the pole mass (see the "Note on Quark Masses").

[1] ALEXANDROU 21 determines the quark mass using a lattice calculation of the meson and baryon masses with a twisted mass fermion action. We have converted $\overline{m}_c(3\text{ GeV}) = 1.036 \pm 0.017 \pm 0.015_{-0.008}$ to $\overline{m}_c(\overline{m}_c)$. The simulations are carried out using 2+1+1 dynamical quarks with $m_u = m_d \neq m_s \neq m_c$, including gauge ensembles close to the physical pion point.
[2] HEITGER 21 determines the charm quark mass using a $n_f = 2{+}1$ flavor lattice QCD simulation with non-perturbatively O(a) improved Wilson fermions. They also determine $\overline{m}_c(3\text{ GeV}) = 1.007 \pm 0.016$ GeV.
[3] HATTON 20 determines the charm quark mass with a lattice QCD + quenched QED simulation using the HISQ action and including $n_f = 2{+}1{+}1$ flavors of sea quarks. m_c is tuned from the J/ψ meson mass giving $\overline{m}_c(3\text{ GeV}) = 0.9841 \pm 0.0051$ GeV.
[4] NARISON 20 determines the quark mass using QCD Laplace sum rules from the B_c mass, combined with previous determinations of the QCD condensates and c and b masses.
[5] ABRAMOWICZ 18 determine $\overline{m}_c(\overline{m}_c) = 1.290^{+0.046+0.062+0.003}_{-0.041-0.014-0.031}$ from the production of c quarks in ep collisions at HERA using combined H1 and ZEUS data. The experimental/fitting errors, and those from modeling and parameterization have been combined in quadrature.
[6] BAZAVOV 18 determine the quark masses using a lattice computation with staggered fermions and four active quark flavors.
[7] LYTLE 18 combined with CHAKRABORTY 15 determine $\overline{m}_c(3\text{ GeV}) = 0.9874(48)$ GeV from a lattice simulation with $n_f = 2{+}1{+}1$ flavors. They also determine the quoted value $\overline{m}_c(\overline{m}_c)$ for $n_f = 4$ dynamical flavors.
[8] PESET 18 determine $\overline{m}_c(\overline{m}_c)$ and $\overline{m}_b(\overline{m}_b)$ using an N3LO calculation of the η_c, η_b and B_c masses.
[9] CHETYRKIN 17 determine $\overline{m}_c(\mu = 3\text{ GeV}) = 0.993 \pm 0.008$ GeV and $\overline{m}_c(\overline{m}_c)$ from a four-loop sum-rule computation of the cross-section for $e^+e^- \to$ hadrons in the charm threshold region.
[10] ERLER 17 determine $\overline{m}_c(\overline{m}_c) = 1.272 \pm 0.008$ GeV from a three-loop QCD sum-rule computation of the vector current correlator. This result is for fixed $\alpha_s(M_Z) = 0.1182$. Including an α_s uncertainty of ±0.0016, the charm mass error increases from 8 to 9 MeV.
[11] KIYO 16 determine $\overline{m}_c(\overline{m}_c)$ from the $J/\psi(1S)$ mass at order α_s^3 (N3LO).

[12] DEHNADI 15 determine $\overline{m}_c(\overline{m}_c)$ using sum rules for $e^+e^- \to$ hadrons at order α_s^3 (N3LO), and fitting to both experimental data and lattice results.

[13] CARRASCO 14 is a lattice QCD computation of light quark masses using $2+1+1$ dynamical quarks, with $m_u = m_d \neq m_s \neq m_c$. The u and d quark masses are obtained separately by using the K meson mass splittings and lattice results for the electromagnetic contributions.

[14] ALEKHIN 13 determines m_c from charm production in deep inelastic scattering at HERA using approximate NNLO QCD.

[15] SAMOYLOV 13 determines m_c from a study of charm dimuon production in neutrino-iron scattering using the NLO QCD result for the charm quark production cross section.

[16] BODENSTEIN 11 determine $\overline{m}_c(3\text{ GeV}) = 0.987 \pm 0.009$ GeV and $\overline{m}_c(\overline{m}_c) = 1.278 \pm 0.009$ GeV using QCD sum rules for the charm quark vector current correlator.

[17] LASCHKA 11 determine the c mass from the charmonium spectrum. The theoretical computation uses the heavy $Q\overline{Q}$ potential to order $1/m_Q$ obtained by matching the short-distance perturbative result onto lattice QCD result at larger scales.

[18] AUBERT 10A determine the b- and c-quark masses from a fit to the inclusive decay spectra in semileptonic B decays in the kinetic scheme (and convert it to the $\overline{\text{MS}}$ scheme).

[19] SIGNER 09 determines the c-quark mass using non-relativistic sum rules to analyze the $e^+e^- \to c\overline{c}$ cross-section near threshold. Also determine the PS mass $m_{PS}(\mu_F = 0.7\text{ GeV}) = 1.50 \pm 0.04$ GeV.

[20] NARISON 18A determines simultaneously $\overline{m}_c(\overline{m}_c)$ and the 4-dimension gluon condensate using QCD exponential sum rules and their ratios evaluated at the optimal scale $\mu = 2.85$ GeV at N2LO-N3LO of perturbative QCD and including condensates up to dimension 6–8 in the (axial-)vector and (pseudo-)scalar charmonium channels.

[21] NARISON 18B determines $\overline{m}_c(\overline{m}_c)$ using QCD vector moment sum rules and their ratios at N2LO-N3LO of perturbative QCD and including condensates up to dimension 8.

[22] BERTONE 16 determine $\overline{m}_c(\overline{m}_c)$ from HERA deep inelastic scattering data using the FONLL scheme. Also determine $\overline{m}_c(\overline{m}_c) = 1.318 \pm 0.054^{+0.490}_{-0.022}$ using the fixed flavor number scheme.

[23] CHAKRABORTY 15 is a lattice QCD computation using 2+1+1 dynamical flavors. Moments of pseudoscalar current-current correlators are matched to α_s^3-accurate QCD perturbation theory with the η_c meson mass tuned to experiment.

[24] ABRAMOWICZ 13C determines m_c from charm production in deep inelastic ep scattering, using the QCD prediction at NLO order. The uncertainties from model and parameterization assumptions, and the value of α_s, of ± 0.03, ± 0.02, and ± 0.02 respectively, have been combined in quadrature.

[25] DEHNADI 13 determines m_c using QCD sum rules for the charmonium spectrum and charm continuum to order α_s^3 (N3LO). The statistical and systematic experimental errors of ± 0.006 and ± 0.009 have been combined in quadrature. The theoretical uncertainties ± 0.019 from truncation of the perturbation series, ± 0.010 from α_s, and ± 0.002 from the gluon condensate have been combined in quadrature.

[26] NARISON 13 determines m_c using QCD spectral sum rules to order α_s^2 (NNLO) and including condensates up to dimension 6.

[27] ALEKHIN 12 determines m_c from heavy quark production in deep inelastic scattering at HERA using approximate NNLO QCD.

[28] NARISON 12A determines m_c using sum rules for the vector current correlator to order α_s^3, including the effect of gluon condensates up to dimension eight.

[29] ALEKHIN 11 determines m_c from heavy quark production in deep inelastic scattering using fixed target and HERA data, and approximate NNLO QCD.

[30] BLOSSIER 10 determines quark masses from a computation of the hadron spectrum using n_f=2 dynamical twisted-mass Wilson fermions.

[31] BODENSTEIN 10 determines $\overline{m}_c(3\text{ GeV}) = 1.008 \pm 0.026$ GeV using finite energy sum rules for the vector current correlator. The authors have converted this to $\overline{m}_c(\overline{m}_c)$ using $\alpha_s(M_Z) = 0.1189 \pm 0.0020$.

[32] MCNEILE 10 determines m_c by comparing the order α_s^3 perturbative results for the pseudo-scalar current to lattice simulations with $n_f = 2+1$ sea-quarks by the HPQCD collaboration.

[33] NARISON 10 determines m_c from ratios of moments of vector current correlators computed to order α_s^3 and including the dimension-six gluon condensate.

[34] CHETYRKIN 09 determine m_c and m_b from the $e^+e^- \to Q\overline{Q}$ cross-section and sum rules, using an order α_s^3 computation of the heavy quark vacuum polarization. They also determine $m_c(3\text{ GeV}) = 0.986 \pm 0.013$GeV.

[35] ALLISON 08 determine m_c by comparing four-loop perturbative results for the pseudo-scalar current correlator to lattice simulations by the HPQCD collaboration. The result has been updated in MCNEILE 10.

[36] KUHN 07 determine $\overline{m}_c(\mu = 3\text{ GeV}) = 0.986 \pm 0.013$ GeV and $\overline{m}_c(\overline{m}_c)$ from a four-loop sum-rule computation of the cross-section for $e^+e^- \to$ hadrons in the charm threshold region.

[37] BOUGHEZAL 06 result comes from the first moment of the hadronic production cross-section to order α_s^3.

[38] BUCHMUELLER 06 determine m_b and m_c by a global fit to inclusive B decay spectra.

[39] HOANG 06 determines $\overline{m}_c(\overline{m}_c)$ from a global fit to inclusive B decay data. The B decay distributions were computed to order $\alpha_s^2\beta_0$, and the conversion between different m_c mass schemes to order α_s^3.

[40] AUBERT 04X obtain m_c from a fit to the hadron mass and lepton energy distributions in semileptonic B decay. The paper quotes values in the kinetic scheme. The $\overline{\text{MS}}$ value has been provided by the BABAR collaboration.

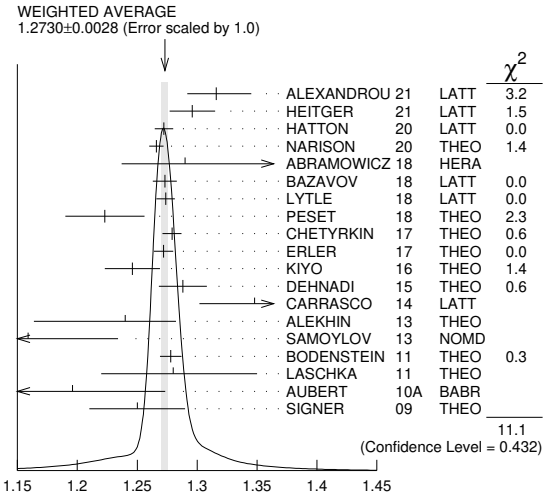
[41] HOANG 04 determines $\overline{m}_c(\overline{m}_c)$ from moments at order α_s^2 of the charm production cross-section in e^+e^- annihilation.

[42] DEDIVITIIS 03 use a quenched lattice computation of heavy-heavy and heavy-light meson masses.

[43] EIDEMULLER 03 determines m_b and m_c using QCD sum rules.

[44] ERLER 03 determines m_b and m_c using QCD sum rules. Includes recent BES data.

[45] ZYABLYUK 03 determines m_c by using QCD sum rules in the pseudoscalar channel and comparing with the η_c mass.



m_c/m_s MASS RATIO

The ratio is that of the $\overline{\text{MS}}$ masses at a common scale, for four dynamical quark flavors.

[1] ALEXANDROU 21 determines the quark mass using a lattice calculation of the meson and baryon masses with a twisted mass fermion action. The simulations are carried out using 2+1+1 dynamical quarks with $m_u = m_d \neq m_s \neq m_c$, including gauge ensembles close to the physical pion point.

[2] BAZAVOV 18 determine the quark masses using a lattice computation with staggered fermions and four active quark flavors.

[3] CHAKRABORTY 15 is a lattice QCD computation on gluon field configurations with 2+1+1 dynamical flavors of HISQ quarks with u/d masses down to the physical value. m_c and m_s are tuned from pseudoscalar meson masses.

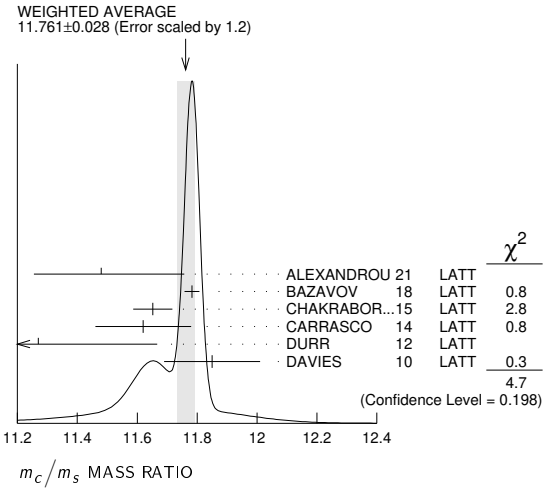
[4] CARRASCO 14 is a lattice QCD computation of light quark masses using $2+1+1$ dynamical quarks, with $m_u = m_d \neq m_s \neq m_c$. The u and d quark masses are obtained separately by using the K meson mass splittings and lattice results for the electromagnetic contributions.

[5] DURR 12 determine m_c/m_s using a lattice computation with $n_f = 2$ dynamical fermions. The result is combined with other determinations of m_c to obtain $m_s(2\text{ GeV}) = 97.0 \pm 2.6 \pm 2.5$ MeV.

[6] DAVIES 10 determine m_c/m_s from meson masses calculated on gluon fields including u, d, and s sea quarks with lattice spacing down to 0.045 fm. The Highly Improved Staggered quark formalism is used for the valence quarks.

[7] BAZAVOV 14A is a lattice computation using 4 dynamical flavors of HISQ fermions.

[8] BLOSSIER 10 determine m_c/m_s from a computation of the hadron spectrum using $n_f = 2$ dynamical twisted-mass Wilson fermions.



m_b/m_c MASS RATIO

The ratio is that of the $\overline{\text{MS}}$ masses at a common scale, for four dynamical quark flavors.

Charge $= -\frac{1}{3}\,e$ Bottom $= -1$

b-QUARK MASS

b-quark mass corresponds to the "running mass" $\overline{m}_b(\mu = \overline{m}_b)$ in the $\overline{\text{MS}}$ scheme. We have converted masses in other schemes to the $\overline{\text{MS}}$ mass using two-loop QCD perturbation theory with $\alpha_s(\mu = \overline{m}_b) = 0.223 \pm 0.008$. The value $4.18^{+0.04}_{-0.03}$ GeV for the $\overline{\text{MS}}$ mass corresponds to 4.78±0.06 GeV for the pole mass, using the two-loop conversion formula. A discussion of masses in different schemes can be found in the "Note on Quark Masses."

[1] APARISI 22 determine m_b at the Higgs mass, $\overline{m}_b(m_H) = 2.60^{+0.36}_{-0.31}$ GeV from Higgs boson decay rates at the LHC, which is used to obtain $\overline{m}_b(\overline{m}_b)$.

[2] HATTON 21 determine $\overline{m}_b(3\text{ GeV}) = 4.513 \pm 0.026$ GeV using a lattice QCD + quenched QED simulation using the HISQ action and including n_f = 2+1+1 flavors of sea quarks, by combining their $\overline{m}_b/\overline{m}_c$ and $\overline{m}_c$ determinations.

[3] NARISON 20 determines the quark mass using QCD Laplace sum rules from the B_c mass, combined with previous determinations of the QCD condensates and c and b masses.

[4] ABRAMOWICZ 18 determine $\overline{m}_b(\overline{m}_b) = 4.049^{+0.104}_{-0.109}{}^{+0.090}_{-0.032}{}^{+0.001}_{-0.031}$ from the production of b quarks in ep collisions at HERA using combined H1 and ZEUS data. The experimental/fitting errors, and those from modeling and parameterization have been combined in quadrature.

[5] BAZAVOV 18 determine the b mass using a lattice computation with staggered fermions and five active quark flavors.

[6] PESET 18 determine $\overline{m}_c(\overline{m}_c)$ and $\overline{m}_b(\overline{m}_b)$ using an N3LO calculation of the η_c, η_b and B_c masses.

[7] KIYO 16 determine $\overline{m}_b(\overline{m}_b)$ from the $\Upsilon(1S)$ mass at order α_s^3 (N3LO).

[8] ALBERTI 15 determine $\overline{m}_b(\overline{m}_b)$ from fits to inclusive $B \to X_c e \overline{\nu}$ decay. They also find $m_b^{\text{kin}}(1\text{ GeV}) = 4.553 \pm 0.020$ GeV.

[9] BENEKE 15 determine $\overline{m}_b(\overline{m}_b)$ using sum rules for $e^+e^- \to$ hadrons at order N3LO including finite m_c effects. They find $m_b^{\text{PS}}(2\text{ GeV}) = 4.532^{+0.013}_{-0.039}$ GeV, and $\overline{m}_b(\overline{m}_b) = 4.193^{+0.022}_{-0.035}$ GeV. The value quoted is obtained using the four-loop conversion given in BENEKE 16.

[10] COLQUHOUN 15 determine $\overline{m}_b(\overline{m}_b)$ from moments of the vector current correlator computed with a lattice simulation using the NRQCD action.

[11] DEHNADI 15 determine $\overline{m}_b(\overline{m}_b)$ using sum rules for $e^+e^- \to$ hadrons at order α_s^3 (N3LO), and fitting to both experimental data and lattice results.

[12] BERNARDONI 14 determine m_b from $n_f = 2$ lattice calculations using heavy quark effective theory non-perturbatively renormalized and matched to QCD at $1/m$ order.

[13] PENIN 14 determine $\overline{m}_b(\overline{m}_b) = 4.169 \pm 0.008 \pm 0.002 \pm 0.002$ using an estimate of the order α_s^3 b-quark vacuum polarization function in the threshold region, including finite m_c effects. The errors of ± 0.008 from theoretical uncertainties, and ± 0.002 from α_s have been combined in quadrature.

[14] LEE 13O determines m_b using lattice calculations of the Υ and B_s binding energies in NRQCD, including three light dynamical quark flavors. The quark mass shift in NRQCD is determined to order α_s^2, with partial α_s^3 contributions.

[15] LUCHA 13 determines m_b from QCD sum rules for heavy-light currents using the lattice value for f_B of 191.5 ± 7.3 GeV.

[16] BODENSTEIN 12 determine m_b using sum rules for the vector current correlator and the $e^+e^- \to Q\overline{Q}$ total cross-section.

[17] DIMOPOULOS 12 determine quark masses from a lattice computation using $n_f = 2$ dynamical flavors of twisted mass fermions.

[18] LASCHKA 11 determine the b mass from the charmonium spectrum. The theoretical computation uses the heavy $Q\overline{Q}$ potential to order $1/m_Q$ obtained by matching the short-distance perturbative result onto lattice QCD result at larger scales.

[19] AUBERT 10A determine the b- and c-quark masses from a fit to the inclusive decay spectra in semileptonic B decays in the kinetic scheme (and convert it to the $\overline{\rm MS}$ scheme).

[20] CHETYRKIN 09 determine m_c and m_b from the $e^+e^- \to Q\overline{Q}$ cross-section and sum rules, using an order α_s^3 (N3LO) computation of the heavy quark vacuum polarization.

[21] SCHWANDA 08 measure moments of the inclusive photon spectrum in $B \to X_s\gamma$ decay to determine m_b^{1S}. We have converted this to $\overline{\rm MS}$ scheme.

[22] NARISON 18A determines $\overline{m}_b(\overline{m}_b)$ as a function of α_s using QCD exponential sum rules and their ratios evaluated at the optimal scale $\mu = 9.5$ GeV at N2LO-N3LO of perturbative QCD and including condensates up to dimension 6–8 in the (axial-)vector and (pseudo-)scalar bottomonium channels.

[23] NARISON 18B determines $\overline{m}_b(\overline{m}_b)$ using QCD vector moment sum rules and their ratios at N2LO-N3LO of perturbative QCD and including condensates up to dimension 8.

[24] ABRAMOWICZ 14A determine $\overline{m}_b(\overline{m}_b) = 4.07 \pm 0.14^{+0.01}_{-0.07} {}^{+0.05}_{-0.00} {}^{+0.08}_{-0.05}$ from the production of b quarks in ep collisions at HERA. The errors due to fitting, modeling, PDF parameterization, and theoretical QCD uncertainties due to the values of α_s, m_c, and the renormalization scale μ have been combined in quadrature.

[25] AYALA 14A determine $\overline{m}_b(\overline{m}_b)$ from the $\Upsilon(1S)$ mass computed to N3LO order in perturbation theory using a renormalon subtracted scheme.

[26] NARISON 13 determines m_b using QCD spectral sum rules to order α_s^2 (NNLO) and including condensates up to dimension 6.

[27] NARISON 13A determines m_b using HQET sum rules to order α_s^2 (NNLO) and the B meson mass and decay constant.

[28] HOANG 12 determine m_b using non-relativistic sum rules for the Υ system at order α_s^2 (NNLO) with renormalization group improvement.

[29] NARISON 12 determines m_b using exponential sum rules for the vector current correlator to order α_s^3, including the effect of gluon condensates up to dimension eight.

[30] Determines m_b to order α_s^3 (N3LO), including the effect of gluon condensates up to dimension eight combining the methods of NARISON 12 and NARISON 12A.

[31] NARISON 12A determines m_b using sum rules for the vector current correlator to order α_s^3, including the effect of gluon condensates up to dimension eight.

[32] MCNEILE 10 determines m_b by comparing order α_s^3 (N3LO) perturbative results for the pseudo-scalar current to lattice simulations with $n_f = 2+1$ sea-quarks by the HPQCD collaboration.

[33] NARISON 10 determines m_b from ratios of moments of vector current correlators computed to order α_s^3 and including the dimension-six gluon condensate. These values are taken from the erratum to that reference.

[34] ABDALLAH 08D determine $\overline{m}_b(M_Z) = 3.76 \pm 1.0$ GeV from a leading order study of four-jet rates at LEP.

[35] GUAZZINI 08 determine $\overline{m}_b(\overline{m}_b)$ from a quenched lattice simulation of heavy meson masses. The ±0.08 is an estimate of the quenching error.

[36] DELLA-MORTE 07 determine $\overline{m}_b(\overline{m}_b)$ from a computation of the spin-averaged B meson mass using quenched lattice HQET at order $1/m$. The ±0.08 is an estimate of the quenching error.

[37] KUHN 07 determine $\overline{m}_b(\mu = 10\ \text{GeV}) = 3.609 \pm 0.025$ GeV and $\overline{m}_b(\overline{m}_b)$ from a four-loop sum-rule computation of the cross-section for $e^+e^- \to$ hadrons in the bottom threshold region.

[38] ABDALLAH 06D determine $m_b(M_Z) = 2.85 \pm 0.32$ GeV from Z-decay three-jet events containing a b-quark.

[39] BOUGHEZAL 06 $\overline{\rm MS}$ scheme result comes from the first moment of the hadronic production cross-section to order α_s^3.

[40] BUCHMUELLER 06 determine m_b and m_c by a global fit to inclusive B decay spectra.

[41] PINEDA 06 $\overline{\rm MS}$ scheme result comes from a partial NNLL evaluation (complete at order α_s^2 (NNLO)) of sum rules of the bottom production cross-section in e^+e^- annihilation.

[42] GRAY 05 determines $\overline{m}_b(\overline{m}_b)$ from a lattice computation of the Υ spectrum. The simulations have 2+1 dynamical light flavors. The b quark is implemented using NRQCD.

[43] AUBERT 04X obtain m_b from a fit to the hadron mass and lepton energy distributions in semileptonic B decay. The paper quotes values in the kinetic scheme. The $\overline{\rm MS}$ value has been provided by the BABAR collaboration.

[44] BAUER 04 determine m_b, m_c and $m_b - m_c$ by a global fit to inclusive B decay spectra.

[45] HOANG 04 determines $\overline{m}_b(\overline{m}_b)$ from moments at order α_s^2 of the bottom production cross-section in e^+e^- annihilation.

[46] MCNEILE 04 use lattice QCD with dynamical light quarks and a static heavy quark to compute the masses of heavy-light mesons.

[47] BAUER 03 determine the b quark mass by a global fit to B decay observables. The experimental data includes lepton energy and hadron invariant mass moments in semileptonic $B \to X_c\ell\nu_\ell$ decay, and the inclusive photon spectrum in $B \to X_s\gamma$ decay. The theoretical expressions used are of order $1/m^3$, and $\alpha_s^2\beta_0$.

[48] BORDES 03 determines m_b using QCD finite energy sum rules to order α_s^2.

[49] CORCELLA 03 determines $\overline{m}_b$ using sum rules computed to order α_s^2. Includes charm quark mass effects.

[50] DEDIVITIIS 03 use a quenched lattice computation of heavy-heavy and heavy-light meson masses.

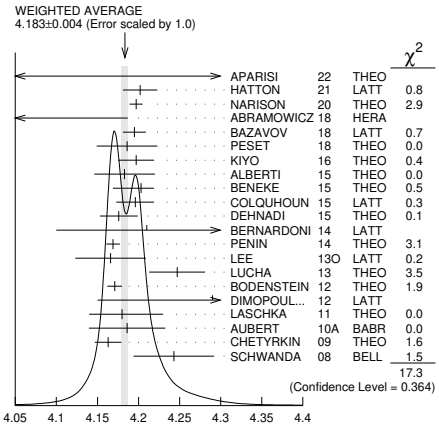
[51] EIDEMULLER 03 determines $\overline{m}_b$ and $\overline{m}_c$ using QCD sum rules.

[52] ERLER 03 determines $\overline{m}_b$ and $\overline{m}_c$ using QCD sum rules. Includes recent BES data.

[53] MAHMOOD 03 determines m_b^{1S} by a fit to the lepton energy moments in $B \to X_c\ell\nu_\ell$ decay. The theoretical expressions used are of order $1/m^3$ and $\alpha_s^2\beta_0$. We have converted their result to the $\overline{\rm MS}$ scheme.

[54] BRAMBILLA 02 determine $\overline{m}_b(\overline{m}_b)$ from a computation of the $\Upsilon(1S)$ mass to order α_s^4, including finite m_c corrections.

[55] PENIN 02 determines $\overline{m}_b$ from the spectrum of the Υ system.



b-QUARK $\overline{\rm MS}$ MASS (GeV)

m_b/m_s MASS RATIO

Top Quark

t-QUARK MASS

We first list the direct measurements of the top quark mass which employ the event kinematics and then list the measurements which extract a top quark mass from the measured $t\bar{t}$ cross-section using theory calculations. A discussion of the definition of the top quark mass in these measurements can be found in the review "The Top Quark."

For earlier search limits see PDG 96, Physical Review **D54** 1 (1996). We no longer include a compilation of indirect top mass determinations from Standard Model Electroweak fits in the Listings (our last compilation can be found in the Listings of the 2007 partial update). For a discussion of current results see the reviews "The Top Quark" and "Electroweak Model and Constraints on New Physics."

t-Quark Mass (Direct Measurements)

The following measurements extract a t-quark mass from the kinematics of $t\bar{t}$ events. They are sensitive to the top quark mass used in the MC generator that is usually interpreted as the pole mass, but the theoretical uncertainty in this interpretation is hard to quantify. See the review "The Top Quark" and references therein for more information.

OUR AVERAGE of 172.57 ± 0.29 GeV is an average of top mass measurements from LHC and Tevatron Runs. The latest Tevatron average, 174.30 ± 0.35 ± 0.54 GeV, was provided by the Tevatron Electroweak Working Group (TEVEWWG).

VALUE (GeV)		*DOCUMENT ID*		*TECN*	*COMMENT*

[1] AAD 23N based on 36.1 fb^{-1} of pp data at $\sqrt{s} = 13$ TeV. The second error is the sum of systematic (±0.66) and that from changing parton-shower gluon recoil scheme (±0.25) uncertainties. The distribution of the invariant mass $m_{\ell\mu}$ (ℓ from W and μ from b-hadron decay) is used, which is less sensitive to jet energy uncertainties and top production modelling.

[2] TUMASYAN 23BB based on 36.3 fb^{-1} of pp data at $\sqrt{s} = 13$ TeV. For each event, the mass is reconstructed from a kinematic fit of the decay products to a $t\bar{t}$ hypothesis. A profile likelihood method is applied using up to four observables per event.

[3] TUMASYAN 23Z based on 138 fb^{-1} of pp data at $\sqrt{s} = 13$ TeV. The second error is the sum of experimental (±0.61), model (±0.47), and theoretical (±0.23) uncertainties. The products of the hadronic decay of a top quark with $p_T > 400$ GeV, in the ℓ + jets channel of $t\bar{t}$, are reconstructed as a single jet. The top quark mass is determined from the normalized differential cross section measurement in the m_{jet} distribution.

[4] TUMASYAN 21G based on 35.9 fb^{-1} of pp data at $\sqrt{s} = 13$ TeV. Events are selected by requiring $1\ell + 2$jets($1b$ jet) final state.

[5] SIRUNYAN 20AR based on 35.9 fb^{-1} of pp data at $\sqrt{s} = 13$ TeV. The products of the hadronic decay of a top quark with $p_T > 400$ GeV, in the ℓ + jets channel of $t\bar{t}$ are reconstructed as a single jet. The top quark mass is determined from the normalized differential cross section measurement in the m_{jet} distribution.

[6] AABOUD 19AC is an ATLAS combination of 7 and 8 TeV top-quark mass determination in the dilepton, lepton + jets, and all jets channels.

[7] SIRUNYAN 19AP based on 35.9 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. A kinematical fit is applied to each event assuming the signal event topology. m_t is determined simultaneously with a jet energy scale factor (JSF). The second error represents stat.+JSF. Modeling uncertainties are larger than in the measurements at $\sqrt{s}$ = 7 and 8 TeV because of the use of new alternative color reconnection models.

[8] SIRUNYAN 19AR based on 35.9 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. Obtained from a simultaneous fit of the cross section and the top quark mass in the POWHEG simulation. The cross section is used also to extract the $\overline{\rm MS}$ mass and the strong coupling constant for different PDF sets.

[9] KHACHATRYAN 16AK based on 19.7 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. Combination of the three top mass measurements in KHACHATRYAN 16AK and with the CMS results at $\sqrt{s}$ = 7 TeV.

[10] TEVEWWG 16 is the latest Tevatron average (July 2016) provided by the Tevatron Electroweak Working Group. It takes correlated uncertainties into account and has a χ^2 of 10.8 for 11 degrees of freedom.

[11] AABOUD 19AC based on 20.2 fb^{-1} in pp collisions at $\sqrt{s}$ = 8 TeV. Uses optimized event selection to suppress less-well-reconstructed events and template fits to determine m_t together with a global jet energy scale factor and a relative b-to-light-jet energy scale factor.

[12] SIRUNYAN 19AP based on 35.9 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. A combined measurement using the lepton+jets and all-jets channels through a single likelihood function. See SIRUNYAN 18DE.

[13] SIRUNYAN 18DE based on 35.9 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. m_t is determined simultaneously with an overall jet energy scale factor constrained by the mass of the hadronically decayed W. Compared to the Run 1 analysis a more advanced treatment of modeling uncertainties are employed, in particular concerning color-reconnection models. Superseded by TUMASYAN 23BB.

[14] AABOUD 17AH based on 20.2 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. Uses template fits to the ratio of the masses of three-jets (from t candidate) and dijets (from W candidate), to suppress jet energy scale uncertainty. Large QCD background is modelled using a data-driven method.

[15] ABAZOV 17B is a combination of measurements of the top quark mass by D0 in the lepton+jets and dilepton channels, using all data collected in Run I (1992–1996) at $\sqrt{s}$ = 1.8 TeV and Run II (2001–2011) at $\sqrt{s}$ = 1.96 TeV of the Tevatron, corresponding to integrated luminosities of 0.1 fb^{-1} and 9.7 fb^{-1}, respectively.

[16] SIRUNYAN 17L based on 19.7 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. m_t is reconstructed from a fit to the invariant mass distribution of $\mu\nu b$, where p_T^{miss} and W mass constraint are used to reconstruct ν momentum. The number of events for various contributions, except for the t-channel single top one, are fixed to the values extracted from simulation. Superseded by TUMASYAN 21G.

[17] SIRUNYAN 17N based on 19.7 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. The fully hadronic decay of a highly-boosted t is reconstructed in the ℓ+jets channel and unfolded at the particle level. The sensitivity of the peak position of the m_{jet} distribution is used to test quality of the modelling by the simulation.

[18] SIRUNYAN 17O based on 19.7 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. Analysis is based on the kinematical observables $M(b\ell)$, M_{T2} and $M(b\ell\nu)$. A fit is performed to determine m_t and an overall jet energy scale factor simultaneously.

[19] AABOUD 16T based on 20.2 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. The analysis is refined using the p_T and invariant mass distributions of ℓ+b-jet system. A combination with measurements from $\sqrt{s}$ = 7 TeV data in the dilepton and lepton+jets channels gives 172.84 ± 0.34 ± 0.61 GeV.

[20] AABOUD 16T is an ATLAS combination of 8 TeV top-quark mass in the dilepton channel with previous measurements from $\sqrt{s}$ = 7 TeV data in the dilepton and lepton + jets channels.

[21] ABAZOV 16 based on 9.7 fb^{-1} of data in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. Employs improved fit to minimize statistical errors and improved jet energy calibration, using lepton + jets mode, which reduces error of jet energy scale. Based on previous determination in ABAZOV 12AB with increased integrated luminosity and improved fit and calibrations.

[22] ABAZOV 16D based on 9.7 fb^{-1} of data in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV, using the matrix element technique. Based on previous determination in ABAZOV 11R with increased integrated luminosity. There is a strong correlation with the determination in ABAZOV 16. (See ABAZOV 17B.)

[23] KHACHATRYAN 16AK based on 19.7 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. Combination of the three top mass measurements in KHACHATRYAN 16AK and with the CMS results at $\sqrt{s}$ = 7 TeV gives 172.44 ± 0.13 ± 0.47 GeV.

[24] The top mass and jet energy scale factor are determined by a fit.

[25] Uses the analytical matrix weighting technique method.

[26] KHACHATRYAN 16AL based on 19.7 fb^{-1} in pp collisions at $\sqrt{s}$ = 8 TeV. Determined from the invariant mass distribution of leptons and reconstructed secondary vertices from b decays using only charged particles. The uncertainty is dominated by modeling of b fragmentation and top p_T distribution.

[27] KHACHATRYAN 16CB based on 666 candidate reconstructed events corresponding to 19.7 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. The measurement exploits correlation of m_t with M($J/\psi\ell$) in the same top quark decay, using a high-purity event sample. A study on modeling of b-quark fragmentation is given in Sec. 3.3.

[28] AAD 15AW based on 4.6 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV. Uses template fits to the ratio of the masses of three-jets (from t candidate) and dijets (from W candidate). Large background from multijet production is modeled with data-driven methods.

[29] AAD 15BF based on 4.6 fb^{-1} in pp collisions at $\sqrt{s}$ = 7 TeV. Using a three-dimensional template likelihood technique the lepton plus jets ($\geq$ 1b-tagged) channel gives 172.33 ± 0.75 ± 1.02 GeV, while exploiting a one dimensional template method using $m_{\ell b}$ the dilepton channel (1 or 2b-tags) gives 173.79 ± 0.54 ± 1.30 GeV. The results are combined.

[30] AALTONEN 15D based on 9.1 fb^{-1} of $p\overline{p}$ data at $\sqrt{s}$ = 1.96 TeV. Uses a template technique to fit a distribution of a variable defined by a linear combination of variables sensitive and insensitive to jet energy scale to optimize reduction of systematic errors. b-tagged and non-b-tagged events are separately analyzed and combined.

[31] Based on 9.3 fb^{-1} of $p\overline{p}$ data at $\sqrt{s}$ = 1.96 TeV. Multivariate algorithm is used to discriminate signal from backgrounds, and templates are used to measure m_t.

[32] Based on 9.7 fb^{-1} of $p\overline{p}$ data at $\sqrt{s}$ = 1.96 TeV. A matrix element method is used to calculate the probability of an event to be signal or background, and the overall jet energy scale is constrained *in situ* by m_W. See ABAZOV 15G for further details.

[33] Based on 3.54 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV. The mass is reconstructed for each event employing a kinematic fit of the jets to a ttbar hypothesis. The combination with the pervious CMS measurements in the dilepton and the lepton+jets channels gives 173.54 ± 0.33 ± 0.96 GeV.

[34] Based on 8.7 fb^{-1} in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. Events with an identified charged lepton or small $\not\!\!E_T$ are rejected from the event sample, so that the measurement is statistically independent from those in the ℓ + jets and all hadronic channels while being sensitive to those events with a τ lepton in the final state.

[35] Based on 5.0 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV. CHATRCHYAN 13S studied events with di-lepton + $\not\!\!E_T$ + $\geq$ 2 b-jets, and looked for kinematical endpoints of MT2, MT2$_T$, and subsystem variables.

[36] AAD 12I based on 1.04 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV. Uses 2d-template analysis (MT) with m_t and jet energy scale factor (JSF) from m_W mass fit.

[37] Based on 8.7 fb^{-1} of data in $p\overline{p}$ collisions at 1.96 TeV. The JES is calibrated by using the dijet mass from the W boson decay.

[38] Use the ME method based on 2.2 fb^{-1} of data in $p\overline{p}$ collisions at 1.96 TeV.

[39] Combination based on up to 5.8 fb^{-1} of data in $p\overline{p}$ collisions at 1.96 TeV.

[40] Based on 5.8 fb^{-1} of data in $p\overline{p}$ collisions at 1.96 TeV the quoted value is m_t = 172.5 ± 1.4(stat)±1.0(JES)±1.1(syst) GeV. The measurement is performed with a liklihood fit technique which simultaneously determines m_t and JES (Jet Energy Scale).

[41] Based on 4.3 fb^{-1} of data in p-pbar collisions at 1.96 TeV. The measurement reduces the JES uncertainty by using the single lepton channel study of ABAZOV 11P.

[42] Combination with the result in 1 fb^{-1} of preceding data reported in ABAZOV 09AH as well as the MWT result of ABAZOV 11R with a statistical correlation of 60%.

[43] Based on 5.0 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV. Uses an analytical matrix weighting technique (AMWT) and full kinematic analysis (KIN).

[44] Based on 5.0 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV. The first error is statistical and JES combined, and the second is systematic. Ideogram method is used to obtain 2D liklihood for the kinematical fit with two parameters mtop and JES.

[45] Based on 3.2 fb^{-1} in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. The first error is from statistics and JES combined, and the latter is from the other systematic uncertainties. The result is obtained using an unbinned maximum likelihood method where the top quark mass and the JES are measured simultaneously, with Δ_{JES} = 0.3 ± 0.3(stat).

[46] Based on 5.7 fb^{-1} in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. Events with an identified charged lepton or small $\not\!\!E_T$ are rejected from the event sample, so that the measurement is statistically independent from those in the ℓ + jets and all hadronic channels while being sensitive to those events with a τ lepton in the final state. Supersedes AALTONEN 07B.

[47] AALTONEN 11E based on 5.6 fb^{-1} in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. Employs a multi-dimensional template likelihood technique where the lepton plus jets (one or two b-tags) channel gives 172.2 ± 1.2 ± 0.9 GeV while the dilepton channel yields 170.3 ± 2.0 ± 3.1 GeV. The results are combined. OUR EVALUATION includes the measurement in the dilepton channel only.

[48] Uses a likelihood fit of the lepton p_T distribution based on 2.7 fb^{-1} in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV.

[49] Based on 3.6 fb^{-1} in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. ABAZOV 11P reports 174.94 ± 0.83±0.78±0.96 GeV, where the first uncertainty is from statistics, the second from JES, and the last from other systematic uncertainties. We combine the JES and systematic uncertainties. A matrix-element method is used where the JES uncertainty is constrained by the W mass. ABAZOV 11P describes a measurement based on 2.6 fb^{-1} that is combined with ABAZOV 08AH, which employs an independent 1 fb^{-1} of data.

[50] Based on a matrix-element method which employs 5.4 fb^{-1} in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. Superseded by ABAZOV 12AB.

[51] Based on 36 pb^{-1} of pp collisions at $\sqrt{s}$ = 7 TeV. A Kinematic Method using b-tagging and an analytical Matrix Weighting Technique give consistent results and are combined. Superseded by CHATRCHYAN 12BA.

[52] Based on 5.6 fb^{-1} in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. The likelihood calculated using a matrix element method gives m_t = 173.0 ± 0.7(stat)±0.6(JES)±0.9(syst) GeV, for a total uncertainty of 1.2 GeV.

[53] Based on 3.4 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. The result is obtained by combining the MT2 variable method and the NWA (Neutrino Weighting Algorithm). The MT2 method alone gives $m_t = 168.0^{+4.8}_{-4.0}$(stat)±2.9(syst) GeV with smaller systematic error due to small JES uncertainty.

[54] Based on 1.9 fb^{-1} in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. The result is from the measurement using the transverse decay length of b-hadrons and that using the transverse momentum of the W decay muons, which are both insensitive to the JES (jet energy scale) uncertainty. OUR EVALUATION uses only the measurement exploiting the decay length significance which yields $166.9^{+9.5}_{-8.5}$(stat)±2.9 (syst) GeV. The measurement that uses the lepton transverse momentum is excluded from the average because of a statistical correlation with other samples.

[55] Based on 2.9 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. The first error is from statistics and JES uncertainty, and the latter is from the other systematics. Neural-network-based kinematical selection of 6 highest E_T jets with a vtx b-tag is used to distinguish signal from background. Superseded by AALTONEN 12G.

[56] Based on 2 fb^{-1} of data at $\sqrt{s}$ = 1.96 TeV. The top mass is obtained from the measurement of the invariant mass of the lepton (e or μ) from W decays and the soft μ in b-jet. The result is insensitive to jet energy scaling.

[57] Based on 1.9 fb^{-1} of data at $\sqrt{s}$ = 1.96 TeV. The first error is from statistics and jet energy scale uncertainty, and the latter is from the other systematics. Matrix element method with effective propagators.

[58] Based on 943 pb^{-1} of data at $\sqrt{s}$ = 1.96 TeV. The first error is from statistical and jet-energy-scale uncertainties, and the latter is from other systematics. AALTONEN 09K selected 6 jet events with one or more vertex b-tags and used the tree-level matrix element to construct template models of signal and background.

[59] Based on 1.9 fb^{-1} of data at $\sqrt{s}$ = 1.96 TeV. The first error is from statistical and jet-energy-scale (JES) uncertainties, and the second is from other systematics. Events with lepton + jets and those with dilepton + jets were simultaneously fit to constrain m_t and JES. Lepton + jets data only give m_t = 171.8 ± 2.2 GeV, and dilepton data only give $m_t = 171.2^{+5.3}_{-5.1}$ GeV.

[60] Based on 2 fb^{-1} of data at $\sqrt{s}$ = 1.96 TeV. Matrix Element method. Optimal selection criteria for candidate events with two high p_T leptons, high $\not\!\!E_T$, and two or more jets with and without b-tag are obtained by neural network with neuroevolution technique to minimize the statistical error of m_t.

[61] Based on 2.9 fb^{-1} of data at $\sqrt{s}$ = 1.96 TeV. Mass m_t is estimated from the likelihood for the eight-fold kinematical solutions in the plane of the azimuthal angles of the two neutrino momenta.

[62] Based on 1 fb^{-1} of data at $\sqrt{s}$ = 1.96 TeV. Events with two identified leptons, and those with one lepton plus one isolated track and a *b*-tag were used to constrain m_t. The result is a combination of the νWT (ν Weighting Technique) result of 176.2 ± 4.8 ± 2.1 GeV and the MWT (Matrix-element Weighting Technique) result of 173.2 ± 4.9 ± 2.0 GeV.

[63] Reports measurement of $170.7^{+4.2}_{-3.9}$ ± 2.6 ± 2.4 GeV based on 1.2 fb^{-1} of data at $\sqrt{s}$ = 1.96 TeV. The last error is due to the theoretical uncertainty on $\sigma_{t\overline{t}}$. Without the cross-section constraint a top mass of $169.7^{+5.2}_{-4.9}$ ± 3.1 GeV is obtained.

[64] Template method.

[65] Result is based on 1 fb^{-1} of data at $\sqrt{s}$ = 1.96 TeV. The first error is from statistics and jet energy scale uncertainty, and the latter is from the other systematics.

[66] Based on 310 pb^{-1} of data at $\sqrt{s}$ = 1.96 TeV.

[67] Ideogram method.

[68] Based on 311 pb^{-1} of data at $\sqrt{s}$ = 1.96 TeV. Events with 4 or more jets with $E_T >$ 15 GeV, significant missing E_T, and secondary vertex *b*-tag are used in the fit. About 44% of the signal acceptance is from $\tau\nu$ + 4 jets. Events with identified e or μ are vetoed to provide a statistically independent measurement.

[69] Based on 1.02 fb^{-1} of data at $\sqrt{s}$ = 1.96 TeV. Superseded by AALTONEN 12G.

[70] Based on 955 pb^{-1} of data $\sqrt{s}$ = 1.96 TeV. m_t and JES (Jet Energy Scale) are fitted simultaneously, and the first error contains the JES contribution of 1.5 GeV.

[71] Matrix element method.

[72] Based on 425 pb^{-1} of data at $\sqrt{s}$ = 1.96 TeV. The first error is a combination of statistics and JES (Jet Energy Scale) uncertainty, which has been measured simultaneously to give JES = 0.989 ± 0.029(stat).

[73] Based on 370 pb^{-1} of data at $\sqrt{s}$ = 1.96 TeV. Combined result of MWT (Matrix-element Weighting Technique) and νWT (ν Weighting Technique) analyses is 178.1 ± 6.7 ± 4.8 GeV.

[74] Based on 1.0 fb^{-1} of data at $\sqrt{s}$ = 1.96 TeV. ABULENCIA 07D improves the matrix element description by including the effects of initial-state radiation.

[75] Based on 695 pb^{-1} of data at $\sqrt{s}$ = 1.96 TeV. The transverse decay length of the *b* hadron is used to determine m_t, and the result is free from the JES (jet energy scale) uncertainty.

[76] Based on ∼ 400 pb^{-1} of data at $\sqrt{s}$ = 1.96 TeV. The first error includes statistical and systematic jet energy scale uncertainties, the second error is from the other systematics. The result is obtained with the *b*-tagging information. The result without *b*-tagging is $169.2^{+5.0}_{-7.4}{}^{+1.5}_{-1.4}$ GeV. Superseded by ABAZOV 08AH.

[77] Based on 318 pb^{-1} of data at $\sqrt{s}$ = 1.96 TeV.

[78] Dynamical likelihood method.

[79] Based on 340 pb^{-1} of data at $\sqrt{s}$ = 1.96 TeV.

[80] Based on 360 pb^{-1} of data at $\sqrt{s}$ = 1.96 TeV.

[81] Based on 110.2 ± 5.8 pb^{-1} at $\sqrt{s}$ = 1.8 TeV.

[82] Based on the all hadronic decays of $t\overline{t}$ pairs. Single *b*-quark tagging via the decay chain $b \to c \to \mu$ was used to select signal enriched multijet events. The result was obtained by the maximum likelihood method after bias correction.

[83] Obtained by re-analysis of the lepton + jets candidate events that led to ABBOTT 98F. It is based upon the maximum likelihood method which makes use of the leading order matrix elements.

[84] Based on 125 ± 7 pb^{-1} of data at $\sqrt{s}$ = 1.8 TeV.

[85] Based on ∼ 106 pb^{-1} of data at $\sqrt{s}$= 1.8 TeV.

[86] Obtained by combining the measurements in the lepton + jets [AFFOLDER 01], all-jets [ABE 97R, ABE 99B], and dilepton [ABE 99B] decay topologies.

[87] Obtained by combining the D0 result m_t (GeV) = 168.4 ± 12.3 ± 3.6 from 6 di-lepton events (see also ABBOTT 98D) and m_t (GeV) = 173.3 ± 5.6 ± 5.5 from lepton+jet events (ABBOTT 98F).

[88] Obtained by combining the CDF results of m_t (GeV)=167.4 ± 10.3 ± 4.8 from 8 dilepton events, m_t (GeV)=175.9 ± 4.8 ± 5.3 from lepton+jet events (ABE 98E), and m_t (GeV)=186.0 ± 10.0 ± 5.7 from all-jet events (ABE 97R). The systematic errors in the latter two measurements are changed in this paper.

[89] See AFFOLDER 01 for details of systematic error re-evaluation.

[90] Based on 109 ± 7 pb^{-1} of data at $\sqrt{s}$ = 1.8 TeV.

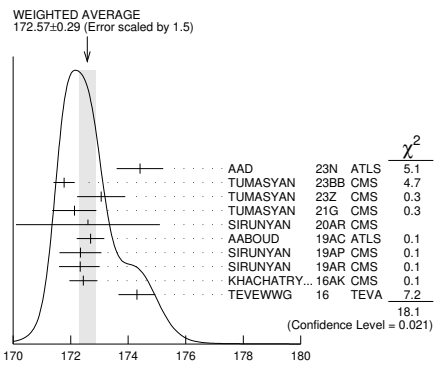
[91] See ABAZOV 04G.

[92] The updated systematic error is listed. See AFFOLDER 01, appendix C.

[93] Obtained by combining the DØ results of m_t(GeV)=168.4 ± 12.3 ± 3.6 from 6 dilepton events and m_t(GeV)=173.3 ± 5.6 ± 5.5 from 77 lepton+jet events.

[94] Obtained by combining the DØ results from dilepton and lepton+jet events, and the CDF results (ABE 99B) from dilepton, lepton+jet events, and all-jet events.

[95] Based on the first observation of all hadronic decays of $t\overline{t}$ pairs. Single *b*-quark tagging with jet-shape variable constraints was used to select signal enriched multi-jet events. The updated systematic error is listed. See AFFOLDER 01, appendix C.



t-Quark Mass (Direct Measurements) (GeV)

t-Quark Mass from Cross-Section Measurements

The top quark $\overline{\text{MS}}$ or pole mass can be extracted from a measurement of $\sigma(t\overline{t})$ by using theory calculations. We quote below the $\overline{\text{MS}}$ mass. See the review "The Top Quark" and references therein for more information.

[1] AAD 19G based on 20.2 fb^{-1} of data in pp collisions at $\sqrt{s}$ = 8 TeV. Normalized $t\overline{t}$ + 1-jet differential cross section as a function of $t\overline{t}j$ invariant mass is measured in the ℓ + jets mode. The unfolded parton-level distribution is compared with the NLO QCD prediction. The three errors are from statitics, systematics, and theory.

[2] Based on 5.3 fb^{-1} in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. ABAZOV 11S uses the measured $t\overline{t}$ production cross section of $8.13^{+1.02}_{-0.90}$ pb [ABAZOV 11E] in the lepton plus jets channel to obtain the top quark $\overline{\text{MS}}$ mass by using an approximate NNLO computation (MOCH 08, LANGENFELD 09). The corresponding top quark pole mass is $167.5^{+5.4}_{-4.9}$ GeV. A different theory calculation (AHRENS 10, AHRENS 10A) is also used and yields $m_t^{\overline{\text{MS}}} = 154.5^{+5.0}_{-4.3}$ GeV.

[3] Based on 1 fb^{-1} of data at $\sqrt{s}$ = 1.96 TeV. Uses the ℓ + jets, $\ell\ell$, and $\ell\tau$ + jets channels. ABAZOV 09AG extract the pole mass of the top quark using two different calculations that yield $169.1^{+5.9}_{-5.2}$ GeV (MOCH 08, LANGENFELD 09) and $168.2^{+5.9}_{-5.4}$ GeV (KIDONAKIS 08).

[4] Based on 1 fb^{-1} of data at $\sqrt{s}$ = 1.96 TeV. Uses the $\ell\ell$ and $\ell\tau$ + jets channels. ABAZOV 09R extract the pole mass of the top quark using two different calculations that yield $173.3^{+9.8}_{-8.6}$ GeV (MOCH 08, LANGENFELD 09) and $171.5^{+9.9}_{-8.8}$ GeV (CACCIARI 08).

[1] AAD 23AY based on 5 fb^{-1} and 20 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV and 8 TeV, respectively. The result is obtained from the combined inclusive cross section measurements and the NNLO+NNLL predictions fixing $\alpha_s(m_Z) = 0.118$.

[2] TUMASYAN 23R based on 36.3 fb^{-1} of data in pp collisions at $\sqrt{s}$ = 13 TeV. Normalized $t\overline{t}$ + 1-jet differential cross section as a function of $t\overline{t}j$ invariant mass is measured in the dilepton mode. The unfolded parton-level distribution is compared with the NLO QCD prediction. The result depends on the PDF and ABMP16NLO is used.

[3] AAD 20Q based on 36.1 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. The result is obtained from the inclusive cross section measurement and the NNLO+NNLL prediction.

[4] AAD 19G based on 20.2 fb^{-1} of data in pp collisions at $\sqrt{s}$ = 8 TeV. Normalized $t\overline{t}$ + 1-jet differential cross section as a function of $t\overline{t}j$ invariant mass is measured in the ℓ + jets mode. The unfolded parton-level distribution is compared with the NLO QCD prediction. The three errors are from statitics, systematics, and theory.

[5] SIRUNYAN 17W based on 2.2 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. Events are categorized according to the jet multiplicity and the number of *b*-tagged jets. The pole mass is obtained from the inclusive cross section measurement and the NNLO prediction.

[6] ABAZOV 16F based on 9.7 fb^{-1} of data in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. The result is obtained from the inclusive cross section measurement and the NNLO+NNLL prediction.

[7] AAD 15BW based on 4.6 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV. Uses normalized differential cross section for $t\overline{t}$ + 1 jet as a function of the inverse of the invariant mass of the $t\overline{t}$ + 1 jet system. The measured cross section is corrected to the parton level. Then a fit to the data using NLO + parton shower prediction is performed.

[8] SIRUNYAN 20BV based on 35.9 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. The error accounts for both experimental and theoretical uncertainties. Events containing two oppositely charged leptons are used. The pole mass is particularly sensitive to the $t\overline{t}$ invariant mass distribution close to the threshold. However, the Coulomb and soft gluon resummation effects are not taken into account, hence, an additional theoretical uncertainty of order +1 GeV is assumed.

[9] AABOUD 17BC based on 20.2 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. The pole mass is extracted from a fit of NLO predictions to eight single lepton and dilepton differential distributions, while simultaneously constraining uncertainties due to PDFs and QCD scales. The three reported uncertainties come from statistics, experimental systematics, and theoretical sources.

[10] KHACHATRYAN 16AW based on 5.0 fb^{-1} of pp collisions at 7 TeV and 19.7 fb^{-1} at 8 TeV. The 7 TeV data include those used in CHATRCHYAN 14. The result is obtained from the inclusive cross sections.
[11] AAD 14AY used $\sigma(t\overline{t})$ for $e\mu$ events. The result is a combination of the measurements $m_t = 171.4 \pm 2.6$ GeV based on 4.6 fb^{-1} of data at 7 TeV and $m_t = 174.1 \pm 2.6$ GeV based on 20.3 fb^{-1} of data at 8 TeV.
[12] CHATRCHYAN 14 used $\sigma(t\overline{t})$ from pp collisions at $\sqrt{s} = 7$ TeV measured in CHATRCHYAN 12AX to obtain m_t(pole) for $\alpha_s(m_Z) = 0.1184 \pm 0.0007$. The errors have been corrected in KHACHATRYAN 14K.

$m_t - m_{\overline{t}}$

Test of CPT conservation. OUR AVERAGE assumes that the systematic uncertainties are uncorrelated.

[1] Based on 20.2 fb^{-1} of pp data at $\sqrt{s} = 8$ TeV. Γ_t is measured using a template fit to the reconstructed invariant mass of the b-jet of the semileptonically decaying top quark and the corresponding lepton, and the angular distance between j_b and j_l in hadronic top decay. Signal templates are generated by reweighting events at parton-level to Breit-Wigner distribution with different Γ_t hypotheses for $m_t = 172.5$ GeV. The result is consistent with the NNLO SM prediction of 1.322 GeV.
[2] Based on 19.7 fb^{-1} of pp data at $\sqrt{s} = 8$ TeV. The result is obtained by combining the measurement of $R = \Gamma(t \to Wb)/\Gamma(t \to Wq\ (q{=}b,s,d))$ and a previous CMS measurement of the t-channel single top production cross section of CHATRCHYAN 12BQ, by using the theoretical calculation of $\Gamma(t \to Wb)$ for $m_t = 172.5$ GeV.
[3] Based on 5.4 fb^{-1} of data in $p\overline{p}$ collisions at 1.96 TeV. $\Gamma(t \to bW) = 1.87^{+0.44}_{-0.40}$ GeV is obtained from the observed t-channel single top quark production cross section, whereas $\mathrm{B}(t \to bW) = 0.90 \pm 0.04$ is used assuming $\sum_q \mathrm{B}(t \to qW) = 1$. The result is valid for $m_t = 172.5$ GeV. See the paper for the values for $m_t = 170$ or 175 GeV.
[4] Based on 8.7 fb^{-1} of data. The two sided 68% CL interval is $1.10 \text{ GeV} < \Gamma_t < 4.05$ GeV for $m_t = 172.5$ GeV.
[5] Based on 2.3 fb^{-1} in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV. ABAZOV 11B extracted Γ_t from the partial width $\Gamma(t \to Wb) = 1.92^{+0.58}_{-0.51}$ GeV measured using the t-channel single top production cross section, and the branching fraction $\mathrm{br}t \to Wb = 0.962^{+0.068}_{-0.066}(\mathrm{stat})^{+0.064}_{-0.052}(\mathrm{syst})$. The $\Gamma(t \to Wb)$ measurement gives the 95% CL lowerbound of $\Gamma(t \to Wb)$ and hence that of Γ_t.
[6] Results are based on 4.3 fb^{-1} of data in $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV. The top quark mass and the hadronically decaying W boson mass are reconstructed for each candidate events and compared with templates of different top quark width. The two sided 68% CL interval is $0.3 \text{ GeV} < \Gamma_t < 4.4$ GeV for $m_t = 172.5$ GeV.
[7] Based on 955 pb^{-1} of $p\overline{p}$ collision data at $\sqrt{s} = 1.96$ TeV. AALTONEN 09M selected $t\overline{t}$ candidate events for the $\ell + \not{E}_T +$ jets channel with one or two b-tags, and examine the decay width dependence of the reconstructed m_t distribution. The result is for m_t =175 GeV, whereas the upper limit is lower for smaller m_t.

[1] Based on 8.7 fb^{-1} of data. This measurement gives $|V_{tb}| = 0.93 \pm 0.04$ and $|V_{tb}| > 0.85$ (95% CL) in the SM.
[2] Based on 19.7 fb^{-1} of pp data at $\sqrt{s} = 8$ TeV. The result is obtained by counting the number of b jets per $t\overline{t}$ signal events in the dilepton channel. The $t\overline{t}$ production cross section is measured to be $\sigma(t\overline{t}) = 238 \pm 1 \pm 15$ pb, in good agreement with the SM prediction and the latest CMS measurement of CHATRCHYAN 14F. The measurement gives $R > 0.995$ (95% CL), or $|V_{tb}| > 0.975$ (95% CL) in the SM, requiring $R \leq 1$.
[3] Based on 8.7 fb^{-1} of $p\overline{p}$ collisions at $\sqrt{s} = 1.96$ TeV. Measure the fraction of $t \to Wb$ decays simultaneously with the $t\overline{t}$ cross section. The correlation coefficient between those two measurements is -0.434. Assume unitarity of the 3×3 CKM matrix and set $|V_{tb}| > 0.89$ at 95% CL.
[4] Based on 5.4 fb^{-1} of data. The error is statistical and systematic combined. The result is a combination of 0.95 ± 0.07 from ℓ + jets channel and 0.86 ± 0.05 from $\ell\ell$ channel. $|V^{tb}| = 0.95 \pm 0.02$ follows from the result by assuming unitarity of the 3x3 CKM matrix.
[5] Result is based on 0.9 fb^{-1} of data. The 95% CL lower bound R > 0.79 gives $|V_{tb}| > 0.89$ (95% CL).

[6] ABAZOV 06K result is from the analysis of $t\bar{t} \to \ell\nu + \geq 3$ jets with 230 pb^{-1} of data at $\sqrt{s} = 1.96$ TeV. It gives R > 0.61 and $|V_{tb}| > 0.78$ at 95% CL. Superseded by ABAZOV 08M.

[7] ACOSTA 05A result is from the analysis of lepton + jets and di-lepton + jets final states of $t\bar{t}$ candidate events with $\sim$ 162 pb^{-1} of data at $\sqrt{s} = 1.96$ TeV. The first error is statistical and the second systematic. It gives R > 0.61, or $|V_{tb}| > 0.78$ at 95% CL.

[8] AFFOLDER 01C measures the top-quark decay width ratio $R = \Gamma(Wb)/\Gamma(Wq)$, where q is a d, s, or b quark, by using the number of events with multiple b tags. The first error is statistical and the second systematic. A numerical integration of the likelihood function gives $R > 0.61$ (0.56) at 90% (95%) CL. By assuming three generation unitarity, $|V_{tb}| = 0.97^{+0.16}_{-0.12}$ or $|V_{tb}| > 0.78$ (0.75) at 90% (95%) CL is obtained. The result is based on 109 pb^{-1} of data at $\sqrt{s} = 1.8$ TeV.

0.111±0.003	[1] AAD	15CC	ATLS	ℓ+jets, $\ell\ell$+jets, $\ell\tau_h$+jets

[1] AAD 15CC based on 4.6 fb^{-1} of pp data at $\sqrt{s} = 7$ TeV. The original value is given by 13.3 ± 0.4 ± 0.5%, which includes electrons from the decay of τ leptons. It is assumed that the top branching ratios to leptons and jets add up to one and that only SM processes contribute to the background. The event selection criteria are optimized for the $\ell\tau_h$ + jets channel. We have converted the original value to eliminate contributions of electrons from τ's, by using the AAD 15CC measurements of the branching ratios to μ and τ channels, as well as the PDG values of τ branching ratios into e and μ channels.

	[4] ABULENCIA	06R	CDF	$\ell\tau$ + jets
	[5] ABE	97V	CDF	$\ell\tau$ + jets

[1] SIRUNYAN 20V based on 35.9 fb^{-1} of pp data at $\sqrt{s} = 13$ TeV. $t\bar{t}$ events are selected in the $t\bar{t} \to (\ell\nu_\ell)(\tau_h\nu_\tau)b\bar{b}$ mode, where τ_h refers to the hadronic decays of τ. The branching ratio is determined with respect to the $t\bar{t}$ inclusive cross section extrapolated from the light dilepton mode. The ratio of the $t\bar{t}$ production cross sections in the $\ell\tau_h$ and $\ell\ell$ channels yields 0.973 ± 0.009 ± 0.066, consistent with lepton universality.

[2] AAD 15CC based on 4.6 fb^{-1} of pp data at $\sqrt{s} = 7$ TeV. The original value is given by 7.0 ± 0.3 ± 0.5%, which includes only the hadronic decay of τ leptons. It is assumed that the top branching ratios to leptons and jets add up to one and that only SM processes contribute to the background. The event selection criteria are optimized for the $\ell\tau_h$ + jets channel. We have converted the original value to include leptonic decays of τ's, by using the AAD 15CC measurements of the branching ratios to e and μ channels, as well as the PDG values of τ branching ratios into e and μ channels.

[3] Based on 9 fb^{-1} of data. The measurement is in the channel $t\bar{t} \to (b\ell\nu)(b\tau\nu)$, where τ decays into hadrons (τ_h), and ℓ (e or μ) include ℓ from τ decays (τ_ℓ). The result is consistent with lepton universality.

[4] ABULENCIA 06R looked for $t\bar{t} \to (\ell\nu_\ell)(\tau\nu_\tau)b\bar{b}$ events in 194 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV. 2 events are found where 1.00 ± 0.17 signal and 1.29 ± 0.25 background events are expected, giving a 95% CL upper bound for the partial width ratio $\Gamma(t \to \tau\nu q) / \Gamma_{SM}(t \to \tau\nu q) < 5.2$.

[5] ABE 97V searched for $t\bar{t} \to (\ell\nu_\ell)(\tau\nu_\tau)b\bar{b}$ events in 109 pb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.8$ TeV. They observed 4 candidate events where one expects $\sim$ 1 signal and $\sim$ 2 background events. Three of the four observed events have jets identified as b candidates.

[1] AAD 23 based on 139 fb^{-1} of data in pp collisions at $\sqrt{s} = 13$ TeV. Anomalous FCNC left-handed and right-handed couplings are searched for through the single top production in association with a photon and in the decay of a top quark in the $t\bar{t}$ production. The SM predictions of the corresponding branching ratios are of the order of 10^{-14}.

[2] KHACHATRYAN 16AS based on 19.8 fb^{-1} of data in pp collisions at $\sqrt{s} = 8$ TeV. FCNC through single top production in association with a photon is searched for in the mode $\mu + \gamma + \not{E}_T + \geq 1$j (0,1$b$). Bounds on the anomalous FCNC couplings are given by $\kappa_{tu\gamma} < 0.025$ and $\kappa_{tc\gamma} < 0.091$.

[3] CHEKANOV 03 looked for single top production via FCNC in the reaction $e^\pm p \to e^\pm$ (t or $\bar{t}$) X in 130.1 pb^{-1} of data at $\sqrt{s}$=300–318 GeV. No evidence for top production and its decay into bW was found. The result is obtained for m_t=175 GeV when B(γc)=B(Zq)=0, where q is a u or c quark. Bounds on the effective t-u-γ and t-u-Z couplings are found in their Fig. 4. The conversion to the constraint listed is from private communication, E. Gallo, January 2004.

[4] AAD 20B based on 81 fb^{-1} of data in pp collisions at $\sqrt{s} = 13$ TeV. FCNC through single top production in association with a photon is searched for in the mode $\ell\gamma + \not{E}_T$ + 1j (b-tag). Anomalous FCNC left-handed and right-handed couplings are searched for, which result in different kinematical properties of top decay such as the lepton distribution. Limits are set on the $tq\gamma$ couplings in an effective field theory.

[5] AARON 09A looked for single top production via FCNC in $e^\pm p$ collisions at HERA with 474 pb^{-1}. The upper bound of the cross section gives the bound on the FCNC coupling $\kappa_{tu\gamma}/\Lambda < 1.03$ TeV^{-1}, which corresponds to the result for $m_t = 175$ GeV.

[6] ABDALLAH 04C looked for single top production via FCNC in the reaction $e^+e^- \to \bar{t}c$ or $\bar{t}u$ in 541 pb^{-1} of data at $\sqrt{s}$=189–208 GeV. No deviation from the SM is found, which leads to the bound on B($t \to \gamma q$), where q is a u or a c quark, for m_t = 175 GeV when B(tZ)=0 is assumed. The conversion to the listed bound is from private communication, O. Yushchenko, April 2005. The bounds on the effective t-q-γ and t-q-Z couplings are given in their Fig. 7 and Table 4, for m_t = 170–180 GeV, where most conservative bounds are found by choosing the chiral couplings to maximize the negative interference between the virtual γ and Z exchange amplitudes.

[7] AKTAS 04 looked for single top production via FCNC in $e^\pm$ collisions at HERA with 118.3 pb^{-1}, and found 5 events in the e or μ channels. By assuming that they are due to statistical fluctuation, the upper bound on the $tu\gamma$ coupling $\kappa_{tu\gamma} < 0.27$ (95% CL) is obtained. The conversion to the partial width limit, when B(γc) = B(Zu) = B(Zc) = 0, is from private communication, E. Perez, May 2005.

[8] ACHARD 02J looked for single top production via FCNC in the reaction $e^+e^- \to \bar{t}c$ or $\bar{t}u$ in 634 pb^{-1} of data at $\sqrt{s}$= 189–209 GeV. No deviation from the SM is found, which leads to a bound on the top-quark decay branching fraction B(γq), where q is a u or c quark. The bound assumes B(Zq)=0 and is for m_t= 175 GeV; bounds for m_t=170 GeV and 180 GeV and B(Zq) ≠ 0 are given in Fig. 5 and Table 7.

[9] ABE 98G looked for $t\bar{t}$ events where one t decays into $q\gamma$ while the other decays into bW. The quoted bound is for $\Gamma(\gamma q)/\Gamma(Wb)$.

[1] AAD 23AS based on 139 fb^{-1} of data in pp collisions at $\sqrt{s} = 13$ TeV. Anomalous FCNC left-handed and right-handed couplings are searched for through the single top production in association with a Z boson and in the decay of a top quark in the $t\bar{t}$ production. Events with $3\ell + \geq 1$ jet(s) ($1b$-tagged) + $\not{E}_T$ are used. The SM predictions of the corresponding branching ratios are of the order of 10^{-14}.

[2] SIRUNYAN 17E based on 19.7 fb^{-1} of pp data at $\sqrt{s} = 8$ TeV. The final states $t\bar{t} \to \ell^+\ell^-\ell'^{\pm}\nu$ + jets ($\ell, \ell' = e, \mu$) are investigated and the cross section $\sigma(pp \to tZq \to \ell\nu b\ell^+\ell^- q) = 10^{+8}_{-7}$ fb is measured, giving no sign of FCNC decays of the top quark.

[3] AAD 16D based on 20.3 fb^{-1} of pp data at $\sqrt{s} = 8$ TeV. The FCNC decay is searched for in $t\bar{t}$ events in the final state $(bW)(qZ)$ when both W and Z decay leptonically, giving 3 charged leptons.

[4] Based on 36.1 fb^{-1} of pp data at $\sqrt{s} = 13$ TeV. The final states $t\bar{t} \to \ell^+\ell^-\ell'^{\pm}\nu$ + jets ($\ell, \ell' = e, \mu$) are investigated and no significant excess over the SM background contributions is observed.

[5] Based on 19.7 fb^{-1} of pp data at $\sqrt{s} = 8$ TeV. The flavor changing decay is searched for in $t\bar{t}$ events in the final state $(bW)(qZ)$ when both W and Z decay leptoically, giving 3 charged leptons.

[6] CHATRCHYAN 14S combined search limit from this and CHATRCHYAN 13F data.

[7] Based on 5.0 fb^{-1} of pp data at $\sqrt{s} = 7$ TeV. Search for FCNC decays of the top quark in $t\bar{t} \to \ell^+\ell^-\ell'^{\pm}\nu$ + jets ($\ell, \ell' = e, \mu$) final states found no excess of signal events.

[8] Based on 2.1 fb^{-1} of pp data at $\sqrt{s} = 7$ TeV.

[9] Based on 4.1 fb^{-1} of data. ABAZOV 11M searched for FCNC decays of the top quark in $t\bar{t} \to \ell^+\ell^-\ell'^{\pm}\nu$ + jets ($\ell, \ell' = e, \mu$) final states, and absence of the signal gives the bound.

[10] Based on $p\bar{p}$ data of 1.52 fb^{-1}. AALTONEN 09AL compared $t\bar{t} \to WbWb \to \ell\nu bjjb$ and $t\bar{t} \to ZcWb \to \ell\ell cjjb$ decay chains, and absence of the latter signal gives the bound. The result is for 100% longitudinally polarized Z boson and the theoretical $t\bar{t}$ production cross section The results for different Z polarizations and those without the cross section assumption are given in their Table XII.

[11] Result is based on 1.9 fb^{-1} of data at $\sqrt{s} = 1.96$ TeV. $t\bar{t} \to WbZq$ or $ZqZq$ processes have been looked for in $Z + \geq 4$ jet events with and without b-tag. No signal leads to the bound B($t \to Zq$) < 0.037 (0.041) for $m_t = 175$ (170) GeV.

[12] ABDALLAH 04C looked for single top production via FCNC in the reaction $e^+e^- \to \bar{t}c$ or $\bar{t}u$ in 541 pb^{-1} of data at $\sqrt{s}$=189–208 GeV. No deviation from the SM is found, which leads to the bound on B($t \to Zq$), where q is a u or a c quark, for $m_t = 175$ GeV when B($t \to \gamma q$)=0 is assumed. The conversion to the listed bound is from private communication, O. Yushchenko, April 2005. The bounds on the effective t-q-γ and t-q-Z couplings are given in their Fig. 7 and Table 4, for $m_t = 170$–180 GeV, where most conservative bounds are found by choosing the chiral couplings to maximize the negative interference between the virtual γ and Z exchange amplitudes.

[13] ACHARD 02J looked for single top production via FCNC in the reaction $e^+e^- \to \bar{t}c$ or $\bar{t}u$ in 634 pb^{-1} of data at $\sqrt{s}$= 189–209 GeV. No deviation from the SM is found, which leads to a bound on the top-quark decay branching fraction B(Zq), where q is a u or c quark. The bound assumes B(γq)=0 and is for m_t= 175 GeV; bounds for m_t=170 GeV and 180 GeV and B(γq) $\neq$0 are given in Fig. 5 and Table 7. Table 6 gives constraints on t-c-e-e four-fermi contact interactions.

[14] HEISTER 02Q looked for single top production via FCNC in the reaction $e^+e^- \to \bar{t}c$ or $\bar{t}u$ in 214 pb^{-1} of data at $\sqrt{s}$= 204–209 GeV. No deviation from the SM is found, which leads to a bound on the branching fraction B(Zq), where q is a u or c quark. The bound assumes B(γq)=0 and is for m_t= 174 GeV. Bounds on the effective t- (c or u)-γ and t- (c or u)- Z couplings are given in their Fig. 2.

[15] ABBIENDI 01T looked for single top production via FCNC in the reaction $e^+e^- \to \bar{t}c$ or $\bar{t}u$ in 600 pb^{-1} of data at $\sqrt{s}$= 189–209 GeV. No deviation from the SM is found, which leads to bounds on the branching fractions B(Zq) and B(γq), where q is a u or c quark. The result is obtained for m_t= 174 GeV. The upper bound becomes 9.7% (20.6%) for m_t= 169 (179) GeV. Bounds on the effective t- (c or u)-γ and t- (c or u)-Z couplings are given in their Fig. 4.

[16] BARATE 00S looked for single top production via FCNC in the reaction $e^+e^- \to \bar{t}c$ or $\bar{t}u$ in 411 pb^{-1} of data at c.m. energies between 189 and 202 GeV. No deviation from the SM is found, which leads to a bound on the branching fraction. The bound assumes B(γq)=0. Bounds on the effective t- (c or u)-γ and t- (c or u)-Z couplings are given in their Fig. 4.

[17] ABE 98G looked for $t\bar{t}$ events where one t decays into three jets and the other decays into qZ with $Z \to \ell\ell$. The quoted bound is for $\Gamma(Zq)/\Gamma(Wb)$.

[1] TUMASYAN 22A based on 137 fb^{-1} at $\sqrt{s} = 13$ TeV of pp data. The processes considered include both the associated production of a single top quark with a Higgs boson and the decay $t \to Hu$ in $t\bar{t}$ production using $H \to \gamma\gamma$.

[2] AAD 23CJ based on 139 fb^{-1} at $\sqrt{s} = 13$ TeV of pp data. The processes considered include both the associated production of a single top quark with a Higgs boson and the decay $t \to Hu$ in $t\bar{t}$ production using $H \to \gamma\gamma$. Limits on the SMEFT Wilson coefficients are derived.

[3] AAD 23CJ based on 139 fb^{-1} at $\sqrt{s} = 13$ TeV of pp data. The results are combined with searches in the $H \to \gamma\gamma$, $H \to bb$, and $H \to \tau\tau$ final states. Limits on the SMEFT Wilson coefficients are also derived.

[4] AAD 23H based on 139 fb^{-1} at $\sqrt{s} = 13$ TeV of pp data. Uses events with one or two hadronically decaying τ and multiple jets. The limit corresponds to $(3.5^{+1.5}_{-1.0}) \times 10^{-4}$ measurement.

[5] TUMASYAN 22K based on 137 fb^{-1} at $\sqrt{s} = 13$ TeV of pp data. Uses events with one isolated lepton and multiple jets (including $\geq 2b$-jets). Deep neural networks are used for kinematical event reconstruction.

[6] AABOUD 19S based on 36.1 fb^{-1} at $\sqrt{s} = 13$ TeV of pp data. Uses events with one isolated lepton and multiple jets (several of them b-tagged with high purity). A multivariate analysis is performed to distinguish the signal from backgrounds.

[7] AABOUD 19S based on 36.1 fb^{-1} at $\sqrt{s} = 13$ TeV of pp data. Uses events with one or two hadronically decaying τ and multiple jets. A multivariate analysis is performed to distinguish the signal from backgrounds.

[8] AABOUD 19S based on 36.1 fb^{-1} at $\sqrt{s} = 13$ TeV of pp data. The searches using $H \to bb$ and $H \to \tau_h\tau_h$ are combined with searches in diphoton and multilepton final states. The upper limit on the Yukawa coupling $|Y_{tuH}| < 0.066$ (95% CL) is obtained.

[9] AABOUD 18X based on 36.1 fb^{-1} at $\sqrt{s} = 13$ TeV of pp data. $\ell\ell$(same sign) + $\geq$4j mode and $\ell\ell\ell + \geq 2$j mode are targeted and specialized boosted decision trees are used to distinguish signals from backgrounds.

[10] SIRUNYAN 18BC based on 35.9 fb^{-1} at $\sqrt{s} = 13$ TeV of pp data. Two channels $pp \to tH$ and $pp \to t\bar{t}$ in final states with one isolated lepton and >=3 jets with >=2 b jets are considered assuming a single tHu FCNC coupling. Reconstructed kinematical variables are fed into a multivariate analysis and no significant deviation is observed from the predicted background.

[11] AABOUD 17AV based on 36.1 fb^{-1} at $\sqrt{s} = 13$ TeV of pp data. Search for $t\bar{t}$ events, where the other top quark decays hadronically or semi-leptonically.

[12] KHACHATRYAN 17I based on 19.7 fb^{-1} of pp data at $\sqrt{s}$= 8 TeV, using the topologies $t\bar{t} \to Hq$+Wb, where q=u, c.

[13] AAD 15CO based on 20.3 fb^{-1} at $\sqrt{s} = 8$ TeV of pp data. Searches for $t\bar{t}$ events, where the other top quark decays semi-leptonically. Exploits high multiplicity of b-jets and uses a likelihood discriminant. Combining with other ATLAS searches for different Higgs decay modes, B($t \to Hc$) < 0.46% and B($t \to Hu$) < 0.45% are obtained.

[14] AAD 14AA based on 4.7 fb^{-1} at $\sqrt{s} = 7$ TeV and 20.3 fb^{-1} at $\sqrt{s} = 8$ TeV of pp data. The upper-bound is for the sum of Br($t \to Hc$) and Br($t \to Hu$). Search for $t\bar{t}$ events, where the other top quark decays hadronically or semi-leptonically. The upper bound constrains the H-t-c Yukawa couplings $\sqrt{|Y^H_{tc_L}|^2 + |Y^H_{tc_R}|^2} < 0.17$ (95% CL).

0.56 ±0.31	[15] ABAZOV	05G	D0	F_0 = B($t \to W_0 b$)

[1] AAD 20Y based on about 20 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV for each experiment. The first error stands for the sum of the statistical and background uncertainties, and the second error for the remaining systematic uncertainties. The measurements used events with one lepton and different jet multiplicities in the final state. The result is consistent with the NNLO SM prediction of 0.687 ± 0.005 for m_t = 172.8 ± 1.3 GeV.

[2] Based on 8.7 fb^{-1} of data in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV using $t\bar{t}$ events with ℓ + $\not{E}_T$ + $\geq$ 4 jets($\geq$ 1 b), and under the constraint $F_0 + F_+ + F_- = 1$. The statstical errors of F_0 and F_+ are correlated with correlation coefficient $\rho(F_0,F_+) = -0.69$.

[3] Based on 5.0 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV. CHATRCHYAN 13BH studied tt events with large $\not{E}_T$ and ℓ + $\geq$ 4 jets using a constrained kinematic fit.

[4] Based on 1.04 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV. AAD 12BG studied tt events with large $\not{E}_T$ and either ℓ + $\geq$ 4j or $\ell\ell$ + $\geq$ 2j. The uncertainties are not independent, $\rho(F_0,F_-) = -0.96$.

[5] Based on 2.7 and 5.1 fb^{-1} of CDF data in ℓ + jets and dilepton channels, and 5.4 fb^{-1} of D0 data in ℓ + jets and dilepton channels. F_0 = 0.682 ± 0.035 ± 0.046 if F_+ = 0.0017(1), while $F_+ = -0.015 \pm 0.018 \pm 0.030$ if F_0 = 0.688(4), where the assumed fixed values are the SM prediction for m_t = 173.3 ± 1.1 GeV and m_W = 80.399 ± 0.023 GeV.

[6] Results are based on 5.4 fb^{-1} of data in $p\overline{p}$ collisions at 1.96 TeV, including those of ABAZOV 08B. Under the SM constraint of f_0 = 0.698 (for m_t = 173.3 GeV, m_W = 80.399 GeV), $f_+ = 0.010 \pm 0.022 \pm 0.030$ is obtained.

[7] AFFOLDER 00B studied the angular distribution of leptonic decays of W bosons in $t \to Wb$ events. The ratio F_0 is the fraction of the helicity zero (longitudinal) W bosons in the decaying top quark rest frame. B($t \to W_+ b$) is the fraction of positive helicity (right-handed) positive charge W bosons in the top quark decays. It is obtained by assuming the Standard Model value of F_0.

[8] AABOUD 17BB based on 20.2 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. Triple-differential decay rate of top quark in the t-channel single-top production is used to simultaneously determine five generalized Wtb couplings as well as the top polarization. No assumption is made for the other couplings. See this paper for constraints on other couplings not included here. The paper reported f_1, and we converted it to F_0.

[9] KHACHATRYAN 16BU based on 19.8 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV using $t\bar{t}$ events with ℓ + $\not{E}_T$ + $\geq$ 4 jets($\geq$ 2 b). The errors of F_0 and F_- are correlated with a correlation coefficient $\rho(F_0, F_-) = -0.87$. The result is consistent with the NNLO SM prediction of 0.687 ± 0.005 for m_t = 172.8 ± 1.3 GeV.

[10] Results are based on 2.7 fb^{-1} of data in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. F_0 result is obtained by assuming F_+ = 0, while F_+ result is obtained for F_0 = 0.70, the SM value. Model independent fits for the two fractions give $F_0 = 0.88 \pm 0.11 \pm 0.06$ and $F_+ = -0.15 \pm 0.07 \pm 0.06$ with correlation coefficient of −0.59. The results are for m_t = 175 GeV.

[11] Results are based on 1.9 fb^{-1} of data in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. F_0 result is obtained assuming F_+ = 0, while F_+ result is obtained for F_0 = 0.70, the SM values. Model independent fits for the two fractions give $F_0 = 0.66 \pm 0.16 \pm 0.05$ and $F_+ = -0.03 \pm 0.06 \pm 0.03$.

[12] Based on 1 fb^{-1} at $\sqrt{s}$ = 1.96 TeV.

[13] Based on 318 pb^{-1} of data at $\sqrt{s}$ = 1.96 TeV.

[14] Based on 200 pb^{-1} of data at $\sqrt{s}$ = 1.96 TeV. $t \to Wb \to \ell\nu b$ (ℓ = e or μ). The errors are stat + syst.

[15] ABAZOV 05G studied the angular distribution of leptonic decays of W bosons in $t\bar{t}$ candidate events with lepton + jets final states, and obtained the fraction of longitudinally polarized W under the constraint of no right-handed current, F_+ = 0. Based on 125 pb^{-1} of data at $\sqrt{s}$ = 1.8 TeV.

[1] AAD 20Y based on about 20 fb^{-1} of pp data at $\sqrt{s} = 8$ TeV for each experiment. The first error stands for the sum of the statistical and background uncertainties, and the second error for the remaining systematic uncertainties. The measurements used events with one lepton and different jet multiplicities in the final state. The result is estimated from the measurements of F_0 and F_- assuming unitarity. The value is consistent with the NNLO SM prediction of 0.0017 ± 0.0001 for $m_t = 172.8 \pm 1.3$ GeV.

[2] Based on 8.7 fb^{-1} of data in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV using $t\bar{t}$ events with ℓ + $\not{E}_T$ + ≥ 4 jets(≥ 1 b), and under the constraint $F_0 + F_+ + F_- = 1$. The statstical errors of F_0 and F_+ are correlated with correlation coefficient $\rho(F_0, F_+) = -0.69$.

[3] Based on 5.0 fb^{-1} of pp data at $\sqrt{s} = 7$ TeV. CHATRCHYAN 13BH studied tt events with large $\not{E}_T$ and $\ell + \geq 4$ jets using a constrained kinematic fit.

[4] Based on 1.04 fb^{-1} of pp data at $\sqrt{s} = 7$ TeV. AAD 12BG studied tt events with large $\not{E}_T$ and either $\ell + \geq 4$j or $\ell\ell + \geq 2$j.

[5] Results are based on 5.4 fb^{-1} of data in $p\bar{p}$ collisions at 1.96 TeV, including those of ABAZOV 08B. Under the SM constraint of $f_0 = 0.698$ (for $m_t = 173.3$ GeV, $m_W = 80.399$ GeV), $f_+ = 0.010 \pm 0.022 \pm 0.030$ is obtained.

[6] AFFOLDER 00B studied the angular distribution of leptonic decays of W bosons in $t \to Wb$ events. The ratio F_0 is the fraction of the helicity zero (longitudinal) W bosons in the decaying top quark rest frame. $B(t \to W_+ b)$ is the fraction of positive helicity (right-handed) positive charge W bosons in the top quark decays. It is obtained by assuming the Standard Model value of F_0.

[7] AABOUD 17BB based on 20.2 fb^{-1} of pp data at $\sqrt{s} = 8$ TeV. Triple-differential decay rate of top quark in the t-channel single-top production is used to simultaneously determine five generalized Wtb couplings as well as the top polarization. No assumption is made for the other couplings. The authors reported $f_1 = 0.30 \pm 0.05$ and $f_1^+ < 0.120$ which we converted to $F_+ = f_1\, f_1^+$. See this paper for constraints on other couplings not included here.

[8] KHACHATRYAN 16BU based on 19.8 fb^{-1} of pp data at $\sqrt{s} = 8$ TeV using $t\bar{t}$ events with $\ell + \not{E}_T + \geq 4$ jets(≥ 2 b). The result is consistent with the NNLO SM prediction of 0.0017 ± 0.0001 for $m_t = 172.8 \pm 1.3$ GeV.

[9] Based on 2.7 and 5.1 fb^{-1} of CDF data in ℓ + jets and dilepton channels, and 5.4 fb^{-1} of D0 data in ℓ + jets and dilepton channels. $F_0 = 0.682 \pm 0.035 \pm 0.046$ if $F_+ = 0.0017(1)$, while $F_+ = -0.015 \pm 0.018 \pm 0.030$ if $F_0 = 0.688(4)$, where the assumed fixed values are the SM prediction for $m_t = 173.3 \pm 1.1$ GeV and $m_W = 80.399 \pm 0.023$ GeV.

[10] Results are based on 2.7 fb^{-1} of data in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV. F_0 result is obtained by assuming $F_+ = 0$, while F_+ result is obtained for $F_0 = 0.70$, the SM value. Model independent fits for the two fractions give $F_0 = 0.88 \pm 0.11 \pm 0.06$ and $F_+ = -0.15 \pm 0.07 \pm 0.06$ with correlation coefficient of −0.59. The results are for $m_t = 175$ GeV.

[11] Results are based on 1.9 fb^{-1} of data in $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV. F_0 result is obtained assuming $F_+ = 0$, while F_+ result is obtained for $F_0 = 0.70$, the SM values. Model independent fits for the two fractions give $F_0 = 0.66 \pm 0.16 \pm 0.05$ and $F_+ = -0.03 \pm 0.06 \pm 0.03$.

[12] Based on 1 fb^{-1} at $\sqrt{s} = 1.96$ TeV.

[13] Based on 370 pb^{-1} of data at $\sqrt{s} = 1.96$ TeV, using the ℓ + jets and dilepton decay channels. The result assumes $F_0 = 0.70$, and it gives $F_+ < 0.23$ at 95% CL.

[14] Based on 318 pb^{-1} of data at $\sqrt{s} = 1.96$ TeV.

[15] Based on 200 pb^{-1} of data at $\sqrt{s} = 1.96$ TeV. $t \to Wb \to \ell\nu b$ ($\ell = e$ or μ). The errors are stat + syst.

[16] ABAZOV 05L studied the angular distribution of leptonic decays of W bosons in $t\bar{t}$ events, where one of the W's from t or $\bar{t}$ decays into e or μ and the other decays hadronically. The fraction of the "+" helicity W boson is obtained by assuming $F_0 = 0.7$, which is the generic prediction for any linear combination of V and A currents. Based on 230 ± 15 pb^{-1} of data at $\sqrt{s} = 1.96$ TeV.

[17] ACOSTA 05D measures the $m^2_{\ell+b}$ distribution in $t\bar{t}$ production events where one or both W's decay leptonically to $\ell = e$ or μ, and finds a bound on the V+A coupling of the tbW vertex. By assuming the SM value of the longitudinal W fraction $F_0 = B(t \to W_0 b) = 0.70$, the bound on F_+ is obtained. If the results are combined with those of AFFOLDER 00B, the bounds become $F_{V+A} < 0.61$ (95% CL) and $F_+ < 0.18$ (95 %CL), respectively. Based on 109 ± 7 pb^{-1} of data at $\sqrt{s} = 1.8$ TeV (run I).

Combined result of the W helicity measurement in $t\bar{t}$ events (ABAZOV 08B) and the search for anomalous tbW couplings in the single top production (ABAZOV 08AI). Constraints when f_1^L and one of the anomalous couplings are simultaneously allowed to vary are given in their Fig. 1 and Table 1.

[8] Result is based on 0.9 fb^{-1} of data at $\sqrt{s}$ = 1.96 TeV. Single top quark production events are used to measure the Lorentz structure of the tbW coupling. The upper bounds on the non-standard couplings are obtained when only one non-standard coupling is allowed to be present together with the SM one, $f_1^L = V_{tb}^*$.

f_2^R

[1] AAD 20Y based on about 20 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV for each experiment. The measurements used events with one lepton and different jet multiplicities in the final state. The measurements of F_0 and F_- are used to set the limit. The limit is obtained by assuming the other couplings to have their SM values.

[2] AABOUD 17BB based on 20.2 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. Triple-differential decay rate of top quark is used to simultaneously determine five generalized Wtb couplings as well as the top polarization. No assumption is made for the other couplings. See this paper for constraints on other couplings not included here.

[3] AABOUD 17I based on 20.2 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. A cut-based analysis is used to discriminate between signal and backgrounds. All anomalous couplings other than $\mathrm{Im}(f)_2^R$ are assumed to be zero. See this paper for a number of other asymmetries and measurements that are not included here.

[4] KHACHATRYAN 17G based on 5.0 and 19.7 fb^{-1} of pp data at $\sqrt{s}$ = 7 and 8 TeV, respectively. A Bayesian neural network technique is used to discriminate between signal and backgrounds. This is a 95% CL exclusion limit obtained by a three-dimensional fit with simultaneous variation of (f_1^L, f_2^L, f_2^R).

[5] AAD 16AK based on 4.6 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV. The results are obtained from an analysis of angular distributions of the decay products of single top quarks, assuming f_1^R=f_2^L=0. The fraction of decays containing transversely polarized W is measured to be $F_+ + F_- = 0.37 \pm 0.07$.

[6] Based on 1.04 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV. AAD 12BG studied $t\bar{t}$ events with large $\not{E}_T$ and either ℓ + ≥ 4j or $\ell\ell$ + ≥ 2j.

[7] Based on 5.4 fb^{-1} of data. For each value of the form factor quoted the other two are assumed to have their SM value. Their Fig. 4 shows two-dimensional posterior probability density distributions for the anomalous couplings.

[8] Based on 5.4 fb^{-1} of data in $p\bar{p}$ collisions at 1.96 TeV. Results are obtained by combining the limits from the W helicity measurements and those from the single top quark production.

[9] Based on 1 fb^{-1} of data at $p\bar{p}$ collisions $\sqrt{s}$ = 1.96 TeV. Combined result of the W helicity measurement in $t\bar{t}$ events (ABAZOV 08B) and the search for anomalous tbW couplings in the single top production (ABAZOV 08AI). Constraints when f_1^L and one of the anomalous couplings are simultaneously allowed to vary are given in their Fig. 1 and Table 1.

[10] Result is based on 0.9 fb^{-1} of data at $\sqrt{s}$ = 1.96 TeV. Single top quark production events are used to measure the Lorentz structure of the tbW coupling. The upper bounds on the non-standard couplings are obtained when only one non-standard coupling is allowed to be present together with the SM one, $f_1^L = V_{tb}^*$.

$|f_{LV} V_{tb}|$

Assumed that the top-quark-related CKM matrix elements obey the relation $|V_{td}|, |V_{ts}| \ll |V_{tb}|$ and a form factor f_{LV} is determined for each production mode and centre-of-mass energy.

[1] ABAZOV 16A based on 9.7 fb^{-1} of data. A matrix element method is used. It corresponds to evidence of spin correlation at 4.2σ and is in agreement with the NLO SM prediction $0.80^{+0.01}_{-0.02}$.

[2] This is a combination of the lepton + jets analysis presented in ABAZOV 12B and the dilepton measurement of ABAZOV 11AE. It provides a 3.1 σ evidence for the $t\bar{t}$ spin correlation.

[3] Based on 5.3 fb^{-1} of data. The error is statistical and systematic combined. A matrix element method is used.
[4] Based on 4.3 fb^{-1} of data. The measurement is based on the angular study of the top quark decay products in the helicity basis.The theory prediction is $\kappa \approx 0.40$.
[5] Based on 5.4 fb^{-1} of data using a matrix element method. The error is statistical and systematic combined. The no-correlation hypothesis is excluded at the 97.7% CL.
[6] Based on 5.4 fb^{-1} of data. The error is statistical and systematic combined. The NLO QCD prediction is C = 0.78 ± 0.03. The neutrino weighting method is used for reconstruction of kinematics.

Spin Correlation in $t\bar{t}$ Production in pp Collisions

Spin correlation, f_{SM}, measures the strength of the correlation between the spins of the pair produced $t\bar{t}$. f_{SM} =1 for the SM, while f_{SM} =0 for no spin correlation.

[1] AAD 22T based on 139 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. The results are obtained from the 95% CL upper limits on the single top-quark productions $\sigma(ug \to t)\cdot$B($t \to bW$)$\cdot$B($W \to \ell\nu$) $<$ 3.0 pb and $\sigma(cg \to t)\cdot$B($t \to bW$)$\cdot$B($W \to \ell\nu$) $<$ 4.7 pb. These are interpreted as limits on couplings in an EFT $|C^{ut}_{uG}|/\Lambda^2 < 0.057$ TeV^{-2} and $|C^{ct}_{uG}|/\Lambda^2 < 0.14$ TeV^{-2}. The results also correspond to B($t \to ug$) $< 6.1\times10^{-5}$ and B($t \to cg$) $< 3.7\times10^{-4}$.
[2] KHACHATRYAN 17G based on 5.0 and 19.7 fb^{-1} of pp data at $\sqrt{s}$ = 7 and 8 TeV, respectively. t-channel single top production is used. The result corresponds to B($t \to ug$) $< 2.0\times10^{-5}$ or B($t \to cg$) $< 4.1\times10^{-4}$.
[3] AAD 16AS based on 20.3 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. The results are obtained from the 95% CL upper limit on the single top-quark production $\sigma(qg \to t)\cdot$B($t \to bW$)B($W \to l\nu$) $<$ 2.9 pb, B($t \to ug$) $< 4.0\times10^{-5}$ and B($t \to cg$) $< 20\times10^{-5}$.
[4] Based on 2.05 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV. The results are obtained from the 95% CL upper limit on the single top-quark production $\sigma(qg \to t)\cdot$B($t \to bW$) $<$ 3.9 pb, for q=u or q=c, B($t \to ug$) $< 5.7\times10^{-5}$ and B($t \to ug$) $< 2.7\times10^{-4}$.
[5] Based on 2.3 fb^{-1} of data in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. Upper limit of single top quark production cross section 0.20 pb and 0.27 pb via FCNC t-u-g and t-c-g couplings, respectively, lead to the bounds without assuming the absence of the other coupling. B($t \to u+g$) $< 2.0\times10^{-4}$ and B($t \to c+g$) $< 3.9\times10^{-3}$ follow.
[6] Based on 2.2 fb^{-1} of data in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. Upper limit of single top quark production cross section $\sigma(u(c)+g \to t)$ $<$ 1.8 pb (95% CL) via FCNC t-u-g and t-c-g couplings lead to the bounds. B($t \to u+g$) $< 3.9\times10^{-4}$ and B($t \to c+g$) $< 5.7\times10^{-3}$ follow.
[7] Result is based on 230 pb^{-1} of data at $\sqrt{s}$ = 1.96 TeV. Absence of single top quark production events via FCNC t-u-g and t-c-g couplings lead to the upper bounds on the dimensioned couplings, κ^{utg}/Λ and κ^{ctg}/Λ, respectively.

t-Quark Yukawa Coupling from $t\bar{t}$ Kinematic Distributions in pp Collisions

The ratio of t-quark Yukawa coupling to its standard model predicted value.

VALUE	DOCUMENT ID		TECN	COMMENT

[1] AAD 20Z based on 139 fb^{-1} of pp data at 13 TeV. Assuming a CP-even coupling the $t\bar{t}H$ process is observed with a significance of 5.2 σ, and the measured $\sigma_{t\bar{t}H}\cdot B_{\gamma\gamma} = 1.64^{+0.38+0.17}_{-0.36-0.14}$ fb. A CP-mixing angle $|\alpha| > 43^\circ$ is excluded at 95% CL.
[2] SIRUNYAN 20AS based on 137 fb^{-1} of pp data at 13 TeV. The $t\bar{t}H$ process is observed with a significance of 6.6 σ, and the measured $\sigma_{t\bar{t}H}\cdot B_{\gamma\gamma} = 1.56^{+0.33+0.09}_{-0.30-0.08}$ fb. The fractional contribution of the CP-odd component is measured to be $f^{t\bar{t}H}_{CP} = 0.00\pm0.33$.
[3] SIRUNYAN 19R based on 35.9 fb^{-1} of pp data at 13 TeV. Multivariate techniques are employed to separate the signal from the dominant $t\bar{t}$+jets background. The result is for m_H = 125 GeV. The measured ratio corresponds to a signal significance of 1.6σ above the background-only hypothesis.
[4] SIRUNYAN 18BD based on 35.9 fb^{-1} of pp data at 13 TeV. A combined fit of signal and background templates to data is performed in six event categories separated by jet and b-jet multiplicities. An upper limit of 3.8 is obtained for the cross section ratio.
[5] SIRUNYAN 18L based on up to 5.1, 19.7, and 35.9 fb^{-1} of pp data at 7, 8, and 13 TeV, respectively. An excess of events is observed, with a significance of 5.2 standard deviations, over the expectation from the background-only hypothesis. The result is for the Higgs boson mass of 125.09 GeV.
[6] Based on 4.5 fb^{-1} of data at 7 TeV and 20.3 fb^{-1} at 8 TeV. The result is for m_H = 125.4 GeV. The measurement constrains the top quark Yukawa coupling strength parameter $\kappa_t = Y_t/Y_t^{SM}$ to be $-1.3 < \kappa_t < 8.0$ (95% CL).
[7] Based on 5.1 fb^{-1} of pp data at 7 TeV and 19.7 fb^{-1} at 8 TeV. The results are obtained by assuming the SM decay branching fractions for the Higgs boson of mass 125.6 GeV. The signal strength for individual Higgs decay channels are given in Fig. 13, and the preferred region in the (κ_V, κ_f) space is given in Fig. 14.

Single t-Quark Production Cross Section in $p\overline{p}$ Collisions at $\sqrt{s}$ = 1.8 TeV

Direct probe of the tbW coupling and possible new physics at $\sqrt{s}$ = 1.8 TeV.

[1] AALTONEN 16 based on 9.5 fb^{-1} of data. This includes, as a part, the result of AALTONEN 14K. Combination of this result with that of AALTONEN 14O gives a s + t cross section of $3.02^{+0.49}_{-0.48}$ pb and $|V_{tb}| > 0.84$ (95% CL).

[2] AALTONEN 15H based on 9.7 fb^{-1} of data per experiment. The result is for m_t = 172.5 GeV, and is a combination of the CDF measurements (AALTONEN 16) and the D0 measurements (ABAZOV 13O) on the t-channel single t-quark production cross section. The result is consistent with the NLO+NNLL SM prediction and gives $|V_{tb}| = 1.02^{+0.06}_{-0.05}$ and $|V_{tb}| > 0.92$ (95% CL).

[3] AALTONEN 15H is a combined measurement of s-channel single top cross section by CDF + D0. AALTONEN 14M is not included.

[4] Based on 9.45 fb^{-1} of data, using neural networks to separate signal from backgrounds. The result is for $m_t = 172.5$ GeV. Combination of this result with the CDF measurement in the 1 lepton channel AALTONEN 14L gives $1.36^{+0.37}_{-0.32}$ pb, consistent with the SM prediction, and is 4.2 sigma away from the background only hypothesis.

[5] Based on 9.4 fb^{-1} of data, using neural networks to separate signal from backgrounds. The result is for $m_t = 172.5$ GeV. The result is 3.8 sigma away from the background only hypothesis.

[6] Based on 9.7 fb^{-1} of data per experiment. The result is for $m_t = 172.5$ GeV, and is a combination of the CDF measurements AALTONEN 14L, AALTONEN 14K and the D0 measurement ABAZOV 13O on the s-channel single t-quark production cross section. The result is consistent with the SM prediction of 1.05 ± 0.06 pb and the significance of the observation is of 6.3 standard deviations.

[7] Based on 7.5 fb^{-1} of data. Neural network is used to discriminate signals (s-, t- and Wt-channel single top production) from backgrounds. The result is consistent with the SM prediction, and gives $|V_{tb}| = 0.95 \pm 0.09(\text{stat + syst}) \pm 0.05(\text{theory})$ and $|V_{tb}| > 0.78$ (95% CL). The result is for $m_t = 172.5$ GeV.

[8] Based on 9.7 fb^{-1} of data. Events with $\ell + \not\!\!E_T$ + 2 or 3 jets (1 or 2 b-tag) are analysed, assuming $m_t = 172.5$ GeV. The combined s- + t-channel cross section gives $|V_{tb}\, f_1^L| = 1.12^{+0.09}_{-0.08}$, or $|V_{tb}| > 0.92$ at 95% CL for $f_1^L = 1$ and a flat prior within $0 \leq |V_{tb}|^2 \leq 1$.

[9] Based on 5.4 fb^{-1} of data. The error is statistical + systematic combined. The results are for $m_t = 172.5$ GeV. Results for other m_t values are given in Table 2 of ABAZOV 11AA.

[10] Based on 5.4 fb^{-1} of data and for $m_t = 172.5$ GeV. The error is statistical + systematic combined. Results for other m_t values are given in Table III of ABAZOV 11AD. The result is obtained by assuming the SM ratio between tb (s-channel) and tqb (t-channel) productions, and gives $|V_{tb}\, f_1^L| = 1.02^{+0.10}_{-0.11}$, or $|V_{tb}| > 0.79$ at 95% CL for a flat prior within $0 < |V_{tb}|^2 < 1$.

[11] Based on 3.2 fb^{-1} of data. For combined s- + t-channel result see AALTONEN 09AT.

[12] Result is based on 2.1 fb^{-1} of data. Events with large missing E_T and jets with at least one b-jet without identified electron or muon are selected. Result is obtained when observed 2.1 σ excess over the background originates from the signal for $m_t = 175$ GeV, giving $|V_{tb}| = 1.24^{+0.34}_{-0.29} \pm 0.07$(theory).

[13] Result is based on 2.3 fb^{-1} of data. Events with isolated $\ell + \not\!\!E_T$ + 2 ,3, 4 jets with one or two b-tags are selected. The analysis assumes $m_t = 170$ GeV.

[14] Result is based on 4.8 fb^{-1} of data. Events with an isolated reconstructed tau lepton, missing E_T + 2, 3 jets with one or two b-tags are selected. When combined with ABAZOV 09Z result for $e + \mu$ channels, the s- and t-channels combined cross section is $3.84^{+0.89}_{-0.83}$ pb.

[15] Based on 3.2 fb^{-1} of data. Events with isolated $\ell + \not\!\!E_T$ + jets with at least one b-tag are analyzed and s- and t-channel single top events are selected by using the likelihood function, matrix element, neural-network, boosted decision tree, likelihood function optimized for s-channel process, and neural-networked based analysis of events with $\not\!\!E_T$ that has sensitivity for $W \to\ \tau\nu$ decays. The result is for $m_t = 175$ GeV, and the mean value decreases by 0.02 pb/GeV for smaller m_t. The signal has 5.0 sigma significance. The result gives $|V_{tb}| = 0.91 \pm 0.11$ (stat+syst) ± 0.07 (theory), or $|V_{tb}| > 0.71$ at 95% CL.

[16] Based on 2.3 fb^{-1} of data. Events with isolated $\ell + \not\!\!E_T + \geq 2$ jets with 1 or 2 b-tags are analyzed and s- and t-channel single top events are selected by using boosted decision tree, Bayesian neural networks and the matrix element method. The signal has 5.0 sigma significance. The result gives $|V_{tb}| = 1.07 \pm 0.12$, or $|V_{tb}| > 0.78$ at 95% CL. The analysis assumes $m_t = 170$ GeV.

[17] Result is based on 2.2 fb^{-1} of data. Events with isolated $\ell + \not\!\!E_T$ + 2, 3 jets with at least one b-tag are selected, and s- and t-channel single top events are selected by using likelihood, matrix element, and neural network discriminants. The result can be interpreted as $|V_{tb}| = 0.88^{+0.13}_{-0.12}$(stat + syst) ± 0.07(theory), and $|V_{tb}| > 0.66$ (95% CL) under the $|V_{tb}| < 1$ constraint.

[18] Result is based on 0.9 fb^{-1} of data. Events with isolated $\ell + \not\!\!E_T$ + 2, 3, 4 jets with one or two b-vertex-tag are selected, and contributions from W + jets, $t\overline{t}$, s- and t-channel single top events are identified by using boosted decision trees, Bayesian neural networks, and matrix element analysis. The result can be interpreted as the measurement of the CKM matrix element $|V_{tb}| = 1.31^{+0.25}_{-0.21}$, or $|V_{tb}| > 0.68$ (95% CL) under the $|V_{tb}| < 1$ constraint.

[19] Result is based on 0.9 fb^{-1} of data. This result constrains V_{tb} to $0.68 < |V_{tb}| \leq 1$ at 95% CL.

[20] ABAZOV 05P bounds single top-quark production from either the s-channel W-exchange process, $q'\overline{q} \to\ t\overline{b}$, or the t-channel W-exchange process, $q'g \to\ qt\overline{b}$, based on ~ 230 pb^{-1} of data.

[21] ACOSTA 05N bounds single top-quark production from the t-channel W-exchange process ($q'g \to\ qt\overline{b}$), the s-channel W-exchange process ($q'\overline{q} \to\ t\overline{b}$), and from the combined cross section of t- and s-channel. Based on $\sim$ 162 pb^{-1} of data.

t-channel Single t Production Cross Section in pp Collisions at $\sqrt{s} = 7$ TeV

Direct probe of the tbW coupling and possible new physics at $\sqrt{s} = 7$ TeV.

[1] AABOUD 19R based on 1.17 to 5.1 fb^{-1} of data from ATLAS and CMS at 7 TeV.

[2] Based on 4.59 fb^{-1} of data, using neural networks for signal and background separation. $\sigma(tq) = 46 \pm 1 \pm 6$ pb and $\sigma(\overline{t}q) = 23 \pm 1 \pm 3$ pb are separately measured, as well as their ratio $R = \sigma(tq)/\sigma(\overline{t}q) = 2.04 \pm 0.13 \pm 0.12$. The results are for $m_t = 172.5$ GeV, and those for other m_t values are given by eq.(4) and Table IV. The measurements give $|V_{tb}| = 1.02 \pm 0.07$ or $|V_{tb}| > 0.88$ (95% CL).

[3] Based on 1.04 fb^{-1} of data. The result gives $|V_{tb}| = 1.13^{+0.14}_{-0.13}$ from the ratio σ(exp)/σ(th), where σ(th) is the SM prediction for $|V_{tb}| = 1$. The 95% CL lower bound of $|V_{tb}| > 0.75$ is found if $|V_{tb}| < 1$ is assumed. $\sigma(t) = 59^{+18}_{-16}$ pb and $\sigma(\overline{t}) = 33^{+13}_{-12}$ pb are found for the separate single t and $\overline{t}$ production cross sections, respectively. The results assume $m_t = 172.5$ GeV for the acceptance.

[4] Based on 1.17 fb^{-1} of data for $\ell = \mu$, 1.56 fb^{-1} of data for $\ell = e$ at 7 TeV collected during 2011. The result gives $|V_{tb}| = 1.020 \pm 0.046(\text{meas}) \pm 0.017(\text{th})$. The 95% CL lower bound of $|V_{tb}| > 0.92$ is found if $|V_{tb}| < 1$ is assumed. The results assume m_t = 172.5 GeV for the acceptance.

[5] Based on 36 pb^{-1} of data. The first error is statistical + systematic combined, the second is luminosity. The result gives $|V_{tb}| = 1.114 \pm 0.22(\text{exp}) \pm 0.02(\text{th})$ from the ratio σ(exp)/σ(th), where σ(th) is the SM prediction for $|V_{tb}| = 1$. The 95% CL lower bound of $|V_{tb}| > 0.62$ (0.68) is found from the 2D (BDT) analysis under the constraint $0 < |V_{tb}|^2 < 1$.

t-channel Single t Production Cross Section in pp Collisions at $\sqrt{s} = 8$ TeV

VALUE (pb)	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •				
87.7 ± 5.8	[1] AABOUD	19R	LHC	combination of ATLAS+CMS
$89.6^{+7.1}_{-6.3}$	[2] AABOUD	17T	ATLS	ℓ+$\not\!\!E_T$+2 j (1b j)
$83.6 \pm 2.3 \pm 7.4$	[3] KHACHATRY...14F		CMS	ℓ+$\not\!\!E_T$+ ≥ 2 j (1,2 b, 1 forward j)

[1] AABOUD 19R based on 12.2 to 20.3 fb^{-1} of data from ATLAS and CMS at 8 TeV.

[2] AABOUD 17T based on 20.2 fb^{-1} of data. A maximum-likelihood fit to neural-network discriminant distributions is used to separate signal and background events. Individual cross sections are measured as $\sigma(tq) = 56.7^{+4.3}_{-3.8}$ pb and $\sigma(\overline{t}q) = 32.9^{+3.0}_{-2.7}$ pb, while their ratio is given by $\sigma(tq)/\sigma(\overline{t}q) = 1.72 \pm 0.09$. A lower limit $|V_{tb}| > 0.92$ (95%

CL) is obtained. Measured total and differential cross sections are described well by the SM.

[3] Based on 19.7 fb^{-1} of data. The t and $\bar{t}$ production cross sections are measured separately as $\sigma_{t-ch.}(t) = 53.8 \pm 1.5 \pm 4.4$ pb and $\sigma_{t-ch.}(\bar{t}) = 27.6 \pm 1.3 \pm 3.7$ pb, respectively, as well as their ratio $R_{t-ch} = \sigma_{t-ch.}(t)/\sigma_{t-ch.}(\bar{t}) = 1.95 \pm 0.10 \pm 0.19$, in agreement with the SM predictions. Combination with a previous CMS result at $\sqrt{s}$ = 7 TeV [CHATRCHYAN 12BQ] gives $|V_{tb}| = 0.998 \pm 0.038 \pm 0.016$. Also obtained is the ratio $R_{8/7} = \sigma_{t-ch.}(8\text{TeV})/\sigma_{t-ch.}(7\text{TeV}) = 1.24 \pm 0.08 \pm 0.12$.

s-channel Single t Production Cross Section in pp Collisions at $\sqrt{s}$ = 8 TeV

[1] SIRUNYAN 20D based on 35.9 fb^{-1} of data. Different categories of jet and b jet multiplicity and multivariate discriminators are used to separate signal and background events. The cross section ratio is measured to be $\sigma(tq)/\sigma(\bar{t}q) = 1.68 \pm 0.02 \pm 0.05$. CKM matrix element is obtained as $|f_{LV} V_{tb}| = 0.98 \pm 0.07(\text{exp}) \pm 0.02(\text{theo})$ where f_{LV} is an anomalous form factor. All results are in agreement with the SM.

[2] AABOUD 17H based on 3.2 fb^{-1} of data. A maximum-likelihood fit to neural-network discriminant distributions is used to separate signal and background events. The third error is for luminosity. The cross section ratio is measured to be $\sigma(tq)/\sigma(\bar{t}q) = 1.72 \pm 0.09 \pm 0.18$. A lower limit $|V_{tb}| > 0.84$ (95% CL) is obtained. All results are in agreement with the SM.

[3] SIRUNYAN 17AA based on 2.2 fb^{-1} of data. A multivariate discriminator is used to separate signal and background events. The four errors are from statistics, experimental systematics, theory, and luminosity. The cross section ratio is measured to be $\sigma(tq)/\sigma(\bar{t}q) = 1.81 \pm 0.18 \pm 0.15$. CKM matrix element is obtained as $|V_{tb}| = 1.05 \pm 0.07(\text{exp}) \pm 0.02(\text{theo})$. All results are in agreement with the SM.

s-channel Single t Production Cross Section in pp Collisions at $\sqrt{s}$ = 13 TeV

$670 \pm 90^{+110}_{-100}$	[2] AABOUD	18BK	ATLS	$H \to b\bar{b}$, WW^* $\tau\tau$, $\gamma\gamma$, ZZ^*

[1] AAD 22Q based on 139 fb^{-1} of data. The measured value includes B($H \to \tau\tau$) and corresponds to the rapidity range $|y_H| < 2.5$. The value is consistent with the SM prediction, where B($H \to \tau\tau$) = 6.3% for m_H = 125.09 GeV.

[2] AABOUD 18BK based on 79.8 fb^{-1} of data. The observed significance is 5.8σ relative to the background-only hypothesis. The measurement is consistent with the NLO SM prediction of 507^{+35}_{-50} fb. See Table 3 and Fig. 5 for measurements of individual modes. Combined with the measurements at 7 and 8 TeV, the observed significance is 6.3σ.

[1] TUMASYAN 22L based on 138 fb^{-1} of data at 13 TeV. The result is for a dilepton invariant masses above 30 GeV. It agrees with the NLO SM prediction of $94.2^{+1.9}_{-1.8}(\text{scale}) \pm 2.5(\text{PDF})$ fb. The ratio of t and $\bar{t}$ production cross sections is measured as $2.37^{+0.56}_{-0.42} \pm 0.27_{-0.13}$. The spin asymmetry is measured to be $0.54 \pm 0.16 \pm 0.06$. Both measurements are in agreement with the SM predictions.

[2] AAD 20AB based on 139 fb^{-1} of data at 13 TeV. Neural networks are used to discriminate tZq signal from backgrounds. The result is for the cross section $\sigma(pp \to t\ell^+\ell^- q)$, including non-resonant dilepton pairs, for dilepton invariant masses above 30 GeV and is consistent with the NLO SM prediction of 102^{+5}_{-2} fb.

[3] SIRUNYAN 19BF based on 77.4 fb^{-1} of data. Two BDT's are used in the analysis: one to discriminate prompt leptons from non-prompt ones; and one to discriminate tZq signal from backgrounds. The result is for the cross section $\sigma(pp \to tZq \to t\ell^+\ell^- q)$ for dilepton invariant masses above 30 GeV and is consistent with the NLO SM prediction of 94.2 $\pm$ 3.1 fb.

[4] AABOUD 18AE based on 36.1 fb^{-1} of data. A multivariate analysis is used to separate the signal from the backgrounds. The result is consistent with the NLO SM prediction of 800 fb with a scale uncertainty of $^{+6.1}_{-7.4}$%.

[5] SIRUNYAN 18Z based on 35.9 fb^{-1} of data. A multivariate analysis is used to separate the signal from the backgrounds. The result is for the cross section $\sigma(pp \to tZq \to Wb\ell^+\ell^- q)$ and is consistent with the NLO SM prediction of $94.2^{+1.9}_{-1.8}(\text{scale}) \pm 2.5(\text{PDF})$ fb. Superseded by SIRUNYAN 19BF.

	[1] AAD	23BN	ATLS	$\gamma + \ell$ + jets + $\not{E}_T$

[1] AAD 23BN measured fiducial cross section for $pp \to t\gamma$ at 13 TeV with 139 fb^{-1} of data. The measured cross section is $688 \pm 23^{+75}_{-71}$ fb, to be compared with the NLO SM prediction of 515^{+36}_{-42} fb.

Single t-Quark Production Cross Section in ep Collisions

VALUE (pb)	CL%	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •					
<0.25	95	[1] AARON	09A	H1	$e^\pm p \to e^\pm t X$
<0.55	95	[2] AKTAS	04	H1	$e^\pm p \to e^\pm t X$
<0.225	95	[3] CHEKANOV	03	ZEUS	$e^\pm p \to e^\pm t X$

[1] AARON 09A looked for single top production via FCNC in $e^\pm p$ collisions at HERA with 474 pb^{-1} of data at $\sqrt{s} = 301$–319 GeV. The result supersedes that of AKTAS 04.

[2] AKTAS 04 looked for single top production via FCNC in $e^\pm$ collisions at HERA with 118.3 pb^{-1}, and found 5 events in the e or μ channels while 1.31 ± 0.22 events are expected from the Standard Model background. No excess was found for the hadronic channel. The observed cross section of $\sigma(ep \to e t X) = 0.29^{+0.15}_{-0.14}$ pb at $\sqrt{s} =$ 319 GeV gives the quoted upper bound if the observed events are due to statistical fluctuation.

[3] CHEKANOV 03 looked in 130.1 pb^{-1} of data at $\sqrt{s} = 301$ and 318 GeV. The limit is for $\sqrt{s} = 318$ GeV and assumes $m_t = 175$ GeV.

$t\bar{t}$ Production Cross Section in $p\bar{p}$ Collisions at $\sqrt{s} = 1.8$ TeV

Only the final combined $t\bar{t}$ production cross sections obtained from Tevatron Run I by the CDF and D0 experiments are quoted below.

[1] ABAZOV 16F based on 9.7 fb^{-1} of data. The result is for $m_t = 172.5$ GeV, and the m_t dependence is shown in Table V and Fig. 9. The result agrees with the NNLO+NNLL SM prediction of $7.35^{+0.23}_{-0.27}$ pb.

[2] Based on 9 fb^{-1} of data. The measurement is in the channel $t\bar{t} \to (b\ell\nu)(b\tau\nu)$, where τ decays into hadrons (τ_h), and ℓ (e or μ) include ℓ from τ decays (τ_ℓ). The result is for $m_t = 173$ GeV.

[3] Based on 8.8 fb^{-1} of data. Combination of CDF and D0 measurements given, respectively, by $\sigma(t\bar{t}$; CDF) $= 7.63 \pm 0.31 \pm 0.36 \pm 0.16$ pb, $\sigma(t\bar{t}$; D0) $= 7.56 \pm 0.20 \pm 0.32 \pm 0.46$ pb. All the results are for $m_t = 172.5$ GeV. The m_t dependence of the mean value is parametrized in eq. (1) and shown in Fig. 2.

[4] Based on 9.7 fb^{-1} of data. Differential cross sections with respect to m_{tt}, $|y(\text{top})|$, E_T(top) are shown in Figs. 9, 10, 11, respectively, and are compared to the predictions of MC models.

[5] Based on 8.8 fb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV.

[6] Based on 8.7 fb^{-1} of $p\bar{p}$ collisions at $\sqrt{s} = 1.96$ TeV. Measure the $t\bar{t}$ cross section simultaneously with the fraction of $t \to Wb$ decays. The correlation coefficient between those two measurements is -0.434. Assume unitarity of the 3×3 CKM matrix and set $|V_{tb}| > 0.89$ at 95% CL.

[7] Based on 2.2 fb^{-1} of data in $p\bar{p}$ collisions at 1.96 TeV. The result assumes the acceptance for $m_t = 172.5$ GeV.

[8] Based on 1.12 fb^{-1} and assumes $m_t = 175$ GeV, where the cross section changes by ± 0.1 pb for every ∓ 1 GeV shift in m_t. AALTONEN 11D fits simultaneously the $t\bar{t}$ production cross section and the b-tagging efficiency and find improvements in both measurements.

[9] Based on 2.7 fb^{-1}. The first error is from statistics and systematics, the second is from luminosity. The result is for $m_t = 175$ GeV. AALTONEN 11W fits simultaneously a jet flavor discriminator between b-, c-, and light-quarks, and find significant reduction in the systematic error.

[10] Based on 2.2 fb^{-1}. The result is for $m_t = 172.5$ GeV. AALTONEN 11Y selects multi-jet events with large $\not\!\!E_T$, and vetoes identified electrons and muons.

[11] Based on 5.3 fb^{-1}. The error is statistical + systematic + luminosity combined. The result is for $m_t = 172.5$ GeV. The results for other m_t values are given in Table XII and eq.(10) of ABAZOV 11E.

[12] Combination of a dilepton measurement presented in ABAZOV 11Z (based on 5.4 fb^{-1}), which yields $7.36^{+0.90}_{-0.79}$ (stat+syst) pb, and the lepton + jets measurement of ABAZOV 11E. The result is for $m_t = 172.5$ GeV. The results for other m_t values is given by eq.(5) of ABAZOV 11A.

[13] Based on 2.8 fb^{-1}. The result is for $m_t = 175$ GeV.

[14] Based on 2.9 fb^{-1}. Result is obtained from the fraction of signal events in the top quark mass measurement in the all hadronic decay channel.

[15] Based on 1.7 fb^{-1}. The result is for $m_t = 175$ GeV. AALTONEN 10V uses soft electrons from b-hadron decays to suppress W+jets background events.

[16] Based on 4.6 fb^{-1}. The result is for $m_t = 172.5$ GeV. The ratio $\sigma(t\bar{t} \to \ell$+jets) / $\sigma(Z/\gamma^* \to \ell\ell)$ is measured and then multiplied by the theoretical $Z/\gamma^* \to \ell\ell$ cross section of $\sigma(Z/\gamma^* \to \ell\ell) = 251.3 \pm 5.0$ pb, which is free from the luminosity error.

[17] Based on 1 fb^{-1}. The result is for $m_t = 175$ GeV. 7.9 ± 2.3 pb is found for $m_t = 170$ GeV. ABAZOV 10I uses a likelihood discriminant to separate signal from background, where the background model was created from lower jet-multiplicity data.

[18] Based on 1 fb^{-1}. The result is for $m_t = 170$ GeV. For $m_t = 175$ GeV, the result is $6.3^{+1.2}_{-1.1}$(stat)± 0.7(syst)± 0.4(lumi) pb. Cross section of $t\bar{t}$ production has been measured in the $t\bar{t} \to \tau_h +$ jets topology, where τ_h denotes hadronically decaying τ leptons. The result for the cross section times the branching ratio is $\sigma(t\bar{t}) \cdot$ B($t\bar{t} \to \tau_h +$ jets) $= 0.60^{+0.23}_{-0.22}{}^{+0.15}_{-0.14} \pm 0.04$ pb for $m_t = 170$ GeV.

[19] Based on 1.1 fb^{-1}. The result is for B($W \to \ell\nu$) = 10.8% and $m_t = 175$ GeV; the mean value is 9.8 for $m_t = 172.5$ GeV and 10.1 for $m_t = 170$ GeV. AALTONEN 09AD used high p_T e or μ with an isolated track to select $t\bar{t}$ decays into dileptons including $\ell = \tau$. The result is based on the candidate event samples with and without vertex b-tag.

[20] Based on 2 fb^{-1}. The result is for $m_t = 175$ GeV; the mean value is 3% higher for $m_t = 170$ GeV and 4% lower for $m_t = 180$ GeV.

[21] Result is based on 1 fb^{-1} of data. The result is for $m_t = 170$ GeV, and the mean value decreases with increasing m_t; see their Fig. 2. The result is obtained after combining ℓ + jets, $\ell\ell$, and $\ell\tau$ final states, and the ratios of the extracted cross sections are $R^{\ell\ell/\ell j} = 0.86^{+0.19}_{-0.17}$ and $R^{\ell\tau/\ell\ell-\ell j} = 0.97^{+0.32}_{-0.29}$, consistent with the SM expectation of R = 1. This leads to the upper bound of B($t \to bH^+$) as a function of m_{H^+}. Results are shown in their Fig. 1 for B($H^+ \to \tau\nu$) = 1 and B($H^+ \to c\bar{s}$) = 1 cases. Comparison of the m_t dependence of the extracted cross section and a partial NNLO prediction gives $m_t = 169.1^{+5.9}_{-5.2}$ GeV.

[22] Result is based on 1 fb^{-1} of data. The result is for $m_t = 170$ GeV, and the mean value changes by -0.07 [m_t(GeV)-170] pb near the reference m_t value. Comparison of the m_t dependence of the extracted cross section and a partial NNLO QCD prediction gives $m_t = 171.5^{+9.9}_{-8.8}$ GeV. The $\ell\tau$ channel alone gives $7.6^{+4.9}_{-4.3}{}^{+3.5}_{-3.4}{}^{+1.4}_{-0.9}$ pb and the $\ell\ell$ channel gives $7.5^{+1.2}_{-1.1}{}^{+0.7}_{-0.6}{}^{+0.7}_{-0.5}$ pb.

[23] Result is based on 0.9 fb^{-1} of data. The first error is from stat + syst, while the latter error is from luminosity. The result is for m_t=175 GeV, and the mean value changes by -0.09 pb·[m_t(GeV)-175].

[24] Result is based on 0.9 fb^{-1} of data. The cross section is obtained from the $\ell + \geq 3$jet event rates with 1 or 2 b-tag, and also from the kinematical likelihood analysis of the $\ell +$ 3, 4 jet events. The result is for m_t=172.6 GeV, and its m_t dependence shown in Fig. 3 leads to the constraint $m_t = 170 \pm 7$ GeV when compared to the SM prediction.

[25] Result is based on 360 pb^{-1} of data. Events with high p_T oppositely charged dileptons $\ell^+\ell^-$ ($\ell = e, \mu$) are used to obtain cross sections for $t\bar{t}$, W^+W^-, and $Z \to \tau^+\tau^-$ production processes simultaneously. The other cross sections are given in Table IV.

[26] Based on 1.02 fb^{-1} of data. Result is for $m_t = 175$ GeV. Secondary vertex b-tag and neural network selections are used to achieve a signal-to-background ratio of about 1/2.

[27] Based on 425 pb^{-1} of data. Result is for $m_t = 175$ GeV. For $m_t = 170.9$ GeV, 7.8 ± 1.8(stat + syst) pb is obtained.

[28] Based on 405 $\pm$ 25 pb^{-1} of data. Result is for $m_t = 175$ GeV. The last error is for luminosity. Secondary vertex b-tag and neural network are used to separate the signal events from the background.

[29] Based on 425 pb^{-1} of data. Assumes $m_t = 175$ GeV.

[30] Based on $\sim$ 425 pb^{-1}. Assuming $m_t = 175$ GeV. The first error is combined statistical and systematic, the second one is luminosity.

[31] Based on $\sim$ 318 pb^{-1}. Assuming $m_t = 178$ GeV. The cross section changes by ± 0.08 pb for each $\mp$ GeV change in the assumed m_t. Result is for at least one b-tag. For at least two b-tagged jets, $t\bar{t}$ signal of significance greater than 5σ is found, and the cross section is $10.1^{+1.6}_{-1.4}{}^{+2.0}_{-1.3}$ pb for $m_t = 178$ GeV.

[32] Based on $\sim$ 311 pb^{-1}. Assuming $m_t = 178$ GeV. For $m_t = 175$ GeV, the result is $6.0 \pm 1.2^{+0.9}_{-0.7}$. This is the first CDF measurement without lepton identification, and hence it has sensitivity to the $W \to \tau\nu$ mode.

[33] ABULENCIA,A 06E measures the $t\bar{t}$ production cross section in the all hadronic decay mode by selecting events with 6 to 8 jets and at least one b-jet. S/B = 1/5 has been achieved. Based on 311 pb^{-1}. Assuming $m_t = 178$ GeV.

[34] Based on $\sim$ 318 pb^{-1}. Assuming $m_t = 178$ GeV. Result is for at least one b-tag. For at least two b-tagged jets, the cross section is $11.1^{+2.3}_{-1.9}{}^{+2.5}_{-1.9}$ pb.

[35] ABAZOV 05Q measures the top-quark pair production cross section with $\sim$ 230 pb^{-1} of data, based on the analysis of W plus n-jet events where W decays into e or μ plus neutrino, and at least one of the jets is b-jet like. The first error is statistical and systematic, and the second accounts for the luminosity uncertainty. The result assumes $m_t = 175$ GeV; the mean value changes by $(175 - m_t(\text{GeV})) \times 0.06$ pb in the mass range 160 to 190 GeV.

[36] ABAZOV 05R measures the top-quark pair production cross section with 224–243 pb^{-1} of data, based on the analysis of events with two charged leptons in the final state. The result assumes $m_t = 175$ GeV; the mean value changes by $(175 - m_t(\text{GeV})) \times 0.08$ pb in the mass range 160 to 190 GeV.

[37] Based on 230 pb^{-1}. Assuming $m_t = 175$ GeV.

[38] Based on 194 pb^{-1}. Assuming $m_t = 175$ GeV.

[39] Based on 194 $\pm$ 11 pb^{-1}. Assuming $m_t = 175$ GeV.

[40] Based on 162 $\pm$ 10 pb^{-1}. Assuming $m_t = 175$ GeV.

[41] ACOSTA 05V measures the top-quark pair production cross section with $\sim$ 162 pb^{-1} data, based on the analysis of W plus n-jet events where W decays into e or μ plus neutrino, and at least one of the jets is b-jet like. Assumes $m_t = 175$ GeV.

[42] ACOSTA 04I measures the top-quark pair production cross section with 197 $\pm$ 12 pb^{-1} data, based on the analysis of events with two charged leptons in the final state. Assumes $m_t = 175$ GeV.

Ratio of the Production Cross Sections of $t\bar{t}\gamma$ to $t\bar{t}$ at $\sqrt{s} = 1.96$ TeV

[1] AABOUD 23 based on 4.6 fb^{-1} of data. The measurement is performed using a multivariate event classifier based on a binary learning algorithm which differentiates $t\bar{t}$ events from backgrounds in a three-dimensional space. The result is in agreement with the NNLO+NNLL SM prediction of $177^{+5}_{-6}(\text{scale}) \pm 9(\text{PDF}+\alpha_s)$ pb for $m_t = 172.5$ GeV. Compared to the measured cross section using the dilepton mode of AAD 14AY, significance of discrepancy is between 1.9σ to 2.1σ.

[2] AAD 23AY based on 5 fb^{-1} of data using $m_t = 172.5$ GeV. The ratio of the combined cross section at $\sqrt{s} = 8$ TeV to this one at $\sqrt{s} = 7$ TeV is determined as 1.363 ± 0.032. The values of the cross sections as well as the ratio are consistent with the NNLO+NNLL SM predictions.

[3] KHACHATRYAN 17B based on 5.0 fb^{-1} of data, using a binned likelihood fit of templates to the data. Also the ratio $\sigma(t\bar{t}; 8\text{ TeV})/\sigma(t\bar{t}; 7\text{ TeV}) = 1.43 \pm 0.04 \pm 0.07 \pm 0.05$ is reported. The results are in agreement with NNLO SM predictions.

[4] KHACHATRYAN 16AW based on 5.0 fb^{-1} of data, using a binned likelihood fit to differential distributions of b-tagged and non-b-tagged jets. The result is in good agreement with NNLO SM predictions.

[5] Based on 4.6 fb^{-1} of data. Uses a template fit to distributions of $\not{E}_T$ and jet multiplicities to measure simultaneously $t\bar{t}$, WW, and $Z/\gamma^* \to \tau\tau$ cross sections, assuming $m_t = 172.5$ GeV.

[6] AAD 15CC based on 4.6 fb^{-1} of data. The event selection criteria are optimized for the $\ell\tau_h$ + jets channel. Using only this channel $183 \pm 9 \pm 23 \pm 3$ pb is derived for the cross section.

[7] AAIJ 15R, based on 1.0 fb^{-1} of data, reports $0.239 \pm 0.053 \pm 0.033 \pm 0.024$ pb cross section for the forward fiducial region $p_T(\mu) > 25$ GeV, $2.0 < \eta(\mu) < 4.5$, 50 GeV $< p_T(b) < 100$ GeV, $2.2 < \eta(b) < 4.2$, $\Delta R(\mu,b) > 0.5$, and $p_T(\mu+b) > 20$ GeV. The three errors are from statistics, systematics, and theory. The result agrees with the SM NLO prediction.

[8] AAD 14AY reports $182.9 \pm 3.1 \pm 4.2 \pm 3.6 \pm 3.3$ pb value based on 4.6 fb^{-1} of data. The four errors are from statistics, systematic, luminosity, and the 0.66% beam energy uncertainty. We have combined the systematic uncertainties in quadrature. The result is for $m_t = 172.5$GeV; for other m_t, $\sigma(m_t) = \sigma(172.5\text{GeV}) \times [1 - 0.0028 \times (m_t - 172.5\text{GeV})]$. The result is consistent with the SM prediction at NNLO.

[9] Based on 1.67 fb^{-1} of data. The result uses the acceptance for $m_t = 172.5$ GeV.

[10] Based on 3.54 fb^{-1} of data.

[11] Based on 2.3 fb^{-1} of data.

[12] Based on 3.9 fb^{-1} of data.

[13] Based on 35 pb^{-1} of data for an assumed top quark mass of $m_t = 172.5$ GeV.

[14] Based on 0.70 fb^{-1} of data. The 3 errors are from statistics, systematics, and luminosity. The result uses the acceptance for $m_t = 172.5$ GeV.

[15] Based on 35 pb^{-1} of data. The 3 errors are from statistics, systematics, and luminosity. The result uses the acceptance for $m_t = 172.5$ GeV and $173 \pm 17^{+18}_{-16} \pm 6$ pb is found without the b-tag.

[16] Based on 2.05 fb^{-1} of data. The hadronic τ candidates are selected using a BDT technique. The 3 errors are from statistics, systematics, and luminosity. The result uses the acceptance for $m_t = 172.5$ GeV.

[17] Based on 2.0 fb^{-1} and 2.2 fb^{-1} of data for $\ell = e$ and $\ell = \mu$, respectively. The 3 errors are from statistics, systematics, and luminosity. The result uses the acceptance for $m_t = 172.5$ GeV.

[18] Based on 2.3 fb^{-1} of data. The 3 errors are from statistics, systematics, and luminosity. The result uses the profile likelihood-ratio (PLB) method and an assumed m_t of 172.5 GeV.

[19] Based on 2.9 pb^{-1} of data. The result for single lepton channels is $142 \pm 34^{+50}_{-31}$ pb, while for the dilepton channels is $151^{+78}_{-62}{}^{+37}_{-24}$ pb.

[20] Result is based on 36 pb^{-1} of data. The first uncertainty corresponds to the statistical and systematic uncertainties, and the second corresponds to the luminosity.

[21] Based on 36 pb^{-1} of data. The ratio of $t\bar{t}$ and Z/γ^* cross sections is measured as $\sigma(pp \to t\bar{t})/\sigma(pp \to Z/\gamma^* \to e^+e^-/\mu^+\mu^-) = 0.175 \pm 0.018(\text{stat}) \pm 0.015(\text{syst})$ for $60 < m_{\ell\ell} < 120$ GeV, for which they use an NNLO prediction for the denominator cross section of 972 ± 42 pb.

[22] Result is based on 36 pb^{-1} of data. The first error is from statistical and systematic uncertainties, and the second from luminosity. This is a combination of a measurement in the dilepton channel (CHATRCHYAN 11F) and the measurement in the ℓ + jets channel (CHATRCHYAN 11Z) which yields 150 ± 9 ± 17 ± 6 pb.

[23] Result is based on 3.1 ± 0.3 pb^{-1} of data.

$t\bar{t}$ Production Cross Section in pp Collisions at $\sqrt{s}$ = 8 TeV

Unless otherwise noted the first quoted error is from statistics, the second from systematic uncertainties, and the third from luminosity. If only two errors are quoted the luminosity is included in the systematic uncertainties.

[1] AAD 23AY based on 20 fb^{-1} of data using m_t = 172.5 GeV. The ratio of this cross section at $\sqrt{s}$ = 8 TeV to the combined cross section at $\sqrt{s}$ = 7 TeV is determined as 1.363 ± 0.032. The values of cross sections as well as their ratio are consistent with the NNLO+NNLL SM predictions.

[2] AABOUD 18BH based on 20.2 fb^{-1} of data. The result is for m_t = 172.5 GeV. To reduce effects of uncertainties in the jet energy scale and b-tagging efficiency, they are included as nuisance parameters in the fit of discriminant distributions, after separating selected events into three regions. Furthermore the W+jets background distribution is modelled using Z+jets event data.

[3] AABOUD 17Z based on 20.2 fb^{-1} of data, using the mode $t\bar{t} \to \tau\nu q'\bar{q}b\bar{b}$ with τ decaying hadronically. Single prong and 3 prong decays of τ are separately analyzed. The result is consistent with the SM. The third quoted uncertainty is due to luminosity.

[4] KHACHATRYAN 17B based on 19.6 fb^{-1} of data, using a binned likelihood fit of templates to the data. Also the ratio $\sigma(t\bar{t}; 8\text{ TeV})/\sigma(t\bar{t}; 7\text{ TeV}) = 1.43 \pm 0.04 \pm 0.07 \pm 0.05$ is reported. The results are in agreement with NNLO SM predictions.

[5] AAD 16BK is an update of the value from AAD 14AY using the improved luminosity calibration. The value 242.9 ± 1.7 ± 5.5 ± 5.1 ± 4.2 pb is reported, where we have combined the systematic uncertainties in quadrature. Also the ratio $\sigma(t\bar{t}; 8\text{TeV})/\sigma(t\bar{t}; 7\text{TeV}) = 1.328 \pm 0.024 \pm 0.015 \pm 0.038 \pm 0.001$ has been updated. The former result is consistent with the SM predictions at NNLO, while the latter result is 2.1 σ below the expectation.

[6] KHACHATRYAN 16AW based on 19.7 fb^{-1} of data, using a binned likelihood fit to differential distributions of b-tagged and non-b-tagged jets. The result is in good agreement with NNLO SM predictions.

[7] KHACHATRYAN 16BC based on 18.4 fb^{-1} of data. The last uncertainty is due to luminosity. Cuts on kinematical fit probability and $\Delta R(b,b)$ are imposed. The major QCD background is determined from the data. The result is for m_t = 172.5 GeV and in agreement with the SM prediction. The top quark p_T spectra, also measured, are significantly softer than theoretical predictions.

[8] AAD 15BP based on 20.3 fb^{-1} of data. The result is for m_t = 172.5 GeV and in agreement with the SM prediction 253^{+13}_{-15} pb at NNLO+NNLL. Superseded by AABOUD 18BH.

[9] AAIJ 15R, based on 2.0 fb^{-1} of data, reports 0.289 ± 0.043 ± 0.040 ± 0.029 pb cross section for the forward fiducial region $p_T(j) > 25$ GeV, $2.0 < \eta(\mu) < 4.5$, 50 GeV < $p_T(b) < 100$ GeV, $2.2 < \eta(b) < 4.2$, $\Delta R(\mu,b) > 0.5$, and $p_T(\mu+b) > 20$ GeV. The three errors are from statistics, systematics, and theory. The result agrees with the SM NLO prediction.

[10] AAD 14AY reports 242.4 ± 1.7 ± 5.5 ± 7.5 ± 4.2 pb value based on 20.3 fb^{-1} of data. The four errors are from statistics, systematic, luminosity, and the 0.66% beam energy uncertainty. We have combined the systematic uncertainties in quadrature. The result is for m_t = 172.5GeV; for other m_t, $\sigma(m_t) = \sigma(172.5\text{GeV}) \times [1 - 0.0028 \times (m_t - 172.5\text{GeV})]$. Also measured is the ratio $\sigma(t\bar{t}; 8\text{TeV})/\sigma(t\bar{t}; 7\text{TeV}) = 1.326 \pm 0.024 \pm 0.015 \pm 0.049 \pm 0.001$. The results are consistent with the SM predictions at NNLO.

[11] Based on 5.3 fb^{-1} of data. The result is for m_t = 172.5 GeV, and a parametrization is given in eq.(6.1) for the mean value at other m_t values. The result is in agreement with the SM prediction $252.9^{+6.4}_{-8.6}$ pb at NNLO.

[12] Based on 19.6 fb^{-1} of data. The measurement is in the channel $t\bar{t} \to (b\ell\nu)(b\tau\nu)$, where τ decays into hadrons (τ_h). The result is for m_t = 172.5 GeV. For m_t = 173.3 GeV, the cross section is lower by 3.1 pb.

$t\bar{t}$ Production Cross Section in pp Collisions at $\sqrt{s}$ = 13 TeV

[1] AAD 23S based on 140 fb^{-1} of data at 13 TeV. The second error is the sum of systematic effects (±13), luminosity (±8), and beam energy (±2) uncertainties. This measurement supersedes that of AAD 20Q. The result is in good agreement with the NNLO+NNLL SM prediction.

[2] TUMASYAN 21J result is based on 137 fb^{-1} of data. The last uncertainty is due to the beam luminosity. The result is in agreement with the SM prediction of 832^{+40}_{-46} pb at NNLO+NNLL. Measurements of differential and double-differential cross sections are also presented.

[3] AAD 20AH based on 139 fb^{-1} of data. The last quoted uncertainty is due to the beam luminosity. The result is for m_t = 172.5 GeV and in agreement with the SM prediction of $832^{+20}_{-29}(\text{scale}) \pm 35(\text{PDF}+\alpha(\text{s}))$ pb at NNLO+NNLL.

[4] AAD 20Q reports 826.4 ± 3.6 ± 11.5 ± 15.7 ± 1.9 pb based on 36.1 fb^{-1} of data at 13 TeV. The four errors stem from statistics, systematic effects, luminosity, and beam energy, respectively. We have combined luminosity and beam energy uncertainties in quadrature. The result is in agreement with the SM prediction $832^{+20}_{-29}(\text{scale}) \pm 35(\text{PDF}+\alpha(\text{s}))$ pb at NNLO+NNLL for m_t = 172.5 GeV .

[5] SIRUNYAN 20V based on 35.9 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. The last uncertainty is due to beam luminosity. The $t\bar{t}$ production cross section is measured in the $t\bar{t} \to (\ell\nu_\ell)(\tau_h\nu_\tau)b\bar{b}$ final state, where τ_h refers to the hadronic decays of τ. The result is for m_t = 172.5 GeV and in agreement with the SM prediction at NNLO+NNLL.

[6] SIRUNYAN 19AR based on 35.9 fb^{-1} of data. Obtained from the visible cross section measured using a template fit to multidifferential distributions categorized according to the b-tagged jet multiplicity. The result is for m_t = 172.5 GeV and in agreement with the SM prediction at NNLO+NNLL.

[7] SIRUNYAN 19P reports differential $t\bar{t}$ cross sections measured using dilepton events at 13 TeV with 35.9 fb^{-1} and compared to NLO predictions.

[8] KHACHATRYAN 17N based on 2.2 fb^{-1} of data. The last quoted uncertainty is due to the beam luminosity. This measurement supersedes that of KHACHATRYAN 16J.

[9] SIRUNYAN 17W based on 2.2 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. Events are categorized according to the jet multiplicity and the number of b-tagged jets. A likelihood fit is performed to the event distributions to compare to the NNLO+NNLL prediction.

[10] AABOUD 16R reported value 818 ± 8 ± 27 ± 19 ± 12 pb based on 3.2 fb^{-1} of data. The four errors are from statistics, systematic, luminosity, and beam energy. We have combined the systematic uncertainties in quadrature. The result is in agreement with the SM prediction $832^{+20}_{-29}(\text{scale}) \pm 35(\text{PDF}+\alpha(\text{s}))$ pb at NNLO+NNLL for m_t = 172.5 GeV .

[11] KHACHATRYAN 16J based on 43 pb^{-1} of data. The last uncertainty is due to luminosity. The result is for m_t = 172.5 GeV and in agreement with the SM prediction $832^{+20}_{-29}(\text{scale}) \pm 35(\text{PDF}+\alpha(\text{s}))$ pb at NNLO+NNLL.

[1] AAD 23BC result is based on 140 fb^{-1} of data. The result corresponds to observed significance of 6.1 σ.

[2] HAYRAPETYAN 23B based on 138 fb^{-1} of data. Improvements include the identification of leptons and jets from b hadrons, and from the revised analysis strategy for the signal-background separation by application of machine learning techniques. The result corresponds to the observed significance of 5.6 σ and is in agreement with the NLO (QCD+EW) SM prediction of $13.4^{+1.0}_{-1.8}$ fb including soft-gluon emission corrections at the next-to-leading logarithmic accuracy.

[3] TUMASYAN 23AQ based on up to 138 fb^{-1} of data. The all-hadronic final state is included for the first time.

[4] TUMASYAN 23AQ based on up to 138 fb^{-1} of data. It combines earlier CMS results, giving the observed significance of 4.0σ.

[5] AAD 21BC result is based on 139 fb^{-1} of data. The events are categorized according to the number of jets and how likely to contain b-hadrons and a multivariate analysis is used to discriminate the signal from backgrounds. The result corresponds to observed significance of 1.9 σ.

[6] AAD 21BC combines the results of the four-top-quark production cross section measured from the 1ℓ/opposite-sign 2ℓ channel with that from the same-sign $2\ell/3\ell$ channel (AAD 20AR). The result corresponds to observed significance of 4.7 σ and is consistent within 2.0 σ with the NLO (QCD+EW) SM prediction of 12.0 $\pm$ 2.4 fb.

[7] AAD 20AR based on 139 fb^{-1} of data. Jet multiplicity, jet flavor and event kinematics are used in a multivariate analysis to discriminate the signal from backgrounds. The result corresponds to observed significance of 4.3σ and is consistent within 1.7σ with the NLO (QCD+EW) SM prediction of 12.0 $\pm$ 2.4 fb.

[8] SIRUNYAN 20C based on 137 fb^{-1} of data. Both cut-based and multivariate approaches are taken to discriminate the signal from backgrounds. The result is in agreement with the NLO (QCD+EW) SM prediction of $12.0^{+2.2}_{-2.5}$ fb. The measurement constrains the top quark Yukawa coupling strength parameter to be $|Y_t/Y_t^{SM}| < 1.7$ (95% CL). It is also used to constrain an oblique parameter of the Higgs boson. Superseded by HAYRAPETYAN 23B.

[9] AABOUD 19AP based on 36.1 fb^{-1} of data. The upper limit corresponds to 5.1 times the NLO SM cross section.

[10] AABOUD 19AP limit from data combined with AABOUD 18CE. The upper limit corresponds to 5.3 times the NLO SM cross section. Also a limit on the four-top-quark contact interaction of $|C_{4t}|/\Lambda^2 < 1.9$ TeV^{-2} (95% CL) is obtained in an EFT model.

[11] SIRUNYAN 19CN based on 35.8 fb^{-1} of data, combined with SIRUNYAN 18BU. The results are also interpreted in the effective field theory framework.

[12] SIRUNYAN 19CN based on 35.8 fb^{-1} of data. A multivariate analysis using global event and jet propoerties is performed to discriminate from $t\bar{t}$ background.

[13] AABOUD 18CE based on 36.1 fb^{-1} of proton-proton data taken at $\sqrt{s} = 13$ TeV. Events including a same-sign lepton pair are used. The result is consistent with the NLO SM cross section of 9.2 fb.

[14] SIRUNYAN 18BU based on 35.9 fb^{-1} of proton-proton data taken at $\sqrt{s} = 13$ TeV. Yields from signal regions and control regions defined based on N_{jets}, N_b and N_l are combined in a maximum-likelihood fit. The result is in agreement with the NLO SM prediction $9.2^{+2.9}_{-2.4}$ fb. The measurement constrains the top quark Yukawa coupling strength parameter to be $|Y_t/Y_t^{SM}| < 2.1$ (95% CL).

[15] SIRUNYAN 17AB based on 2.6 fb^{-1} of data. A multivariate analysis is used to discriminate between $t\bar{t}\,t\bar{t}$ signal and $t\bar{t}$ background. A combination with a previous search (CMS, KHACHATRYAN 16BJ) in the same-sign dilepton channel gives an upper limit of 69 fb (95% CL), corresponding to 7.4$\cdot$(SM prediction).

[16] SIRUNYAN 17S based on 35.9 fb^{-1}. The limit is in agreement with the NLO SM prediction $9.2^{+2.9}_{-2.4}$ fb. Superseded by SIRUNYAN 18BU. The signal events are also used to constrain various new physics models.

0.332±0.090	[2] CHATRCHYAN	14AE	CMS	$t\bar{t}(\ell\ell)$ + 0 jet (E_T > 30GeV)
0.436±0.098	[2] CHATRCHYAN	14AE	CMS	$t\bar{t}(\ell\ell)$ + 1 jet (E_T > 30GeV)
0.232±0.125	[2] CHATRCHYAN	14AE	CMS	$t\bar{t}(\ell\ell)$ + ≥ 2 jet (E_T > 30GeV)

[1] Based on 4.6 fb^{-1} of data. Fiducial $t\bar{t}$ production cross section is presented as a function of the jet multiplicity for up to eight jets with the jet p_T threshold of 25, 40, 60, and 80 GeV, and as a function of jet p_T up to the 5th jet. MC models can be discriminated by using data for high jet multiplicity and by p_T distributions of the leading and 5th jet.

[2] Based on 5.0 fb^{-1} of data. Events with two oppositely charged leptons, large $\not{E}_T$ and jets with at least 1 b-tag are used to measure the fraction of $t\bar{t}$ plus additional jets. The gap fraction (n=0 jet rate) as a function of the jet p_T and that of H_T, the scalar sum of the p_T's of additional jets, is shown in Fig. 8.

$t\bar{t}$ Charge Asymmetry (A_C) in pp Collisions at $\sqrt{s} = 7$ TeV

A_C = (N($\Delta|y| > 0$) − N($\Delta|y| < 0$)) / (N($\Delta|y| > 0$) + N($\Delta|y| < 0$)) where $\Delta|y| = |y_t| - |y_{\bar{t}}|$ is the difference between the absolute values of the top and antitop rapidities and N is the number of events with $\Delta|y|$ positive or negative.

[1] ATLAS and CMS combination based on the data of AAD 14I and CHATRCHYAN 12BB. It takes into account the correlations of the measurements and systematic errors. The result is in agreement with the SM prediction (NLO QCD + NLO EW).

[2] AAD 15AJ based on 4.6 fb^{-1} of data. After kinematic reconstruction the top quark momenta are corrected for detector resolution and acceptance effects by unfolding, using parton level information of the MC generators. The lepton charge asymmetry is measured as $A_C^{\ell} = 0.024 \pm 0.015 \pm 0.009$. All the measurements are consistent with the SM predictions.

[3] Based on 4.7 fb^{-1} of data. The result is consistent with the SM prediction of $A_C = 0.0123 \pm 0.0005$. The asymmetry is 0.011 ± 0.018 if restricted to those events where $\beta_Z(t\bar{t}) > 0.6$, which is also consistent with the SM prediction of $0.020^{+0.006}_{-0.007}$.

[4] Based on 5.0 fb^{-1} of data. The lepton charge asymmetry is measured as $A_C^{\ell} = 0.009 \pm 0.0010 \pm 0.006$. A_C^{ℓ} dependences on $m_{t\bar{t}}$, $|y(t\bar{t})|$, and $p_T(t\bar{t})$ are given in Fig. 5. All measurements are consistent with the SM predictions.

[5] Based on 1.04 fb^{-1} of data. The result is consistent with $A_C = 0.006 \pm 0.002$ (MC at NLO). No significant dependence of A_C on $m_{t\bar{t}}$ is observed.

[6] Based on 5.0 fb^{-1} of data at 7 TeV.

[7] Based on 1.09 fb^{-1} of data. The result is consistent with the SM predictions.

[1] ATLAS and CMS combination based on the data of AAD 16AZ and KHACHATRYAN 16AH. It takes into account the correlations of the measurements and systematic errors. A combination of the differential measurements of the charge asymmetry is also presented. The results are in agreement with the SM prediction (NNLO QCD + NLO EW).

[2] AAD 16AE is based on 20.3 fb^{-1} of data. After kinematic reconstruction, the top quark momenta are corrected for detector resolution and acceptance effects by unfolding, using parton level information of the MC generators. The lepton charge asymmetry is measured as $A_C^{\ell\ell} = 0.008 \pm 0.006$. All the measurements are consistent with the SM predictions.

[3] AAD 16AZ based on 20.3 fb^{-1} of data. All the differential and inclusive measurements are statistically limited and consistent with the SM predictions.

[4] AAD 16T based on 20.3 fb^{-1} of data. Uses reconstruction techniques for the decay topology of highly boosted top quarks. The observed asymmetry is transformed by unfolding to a parton-level result in the shown fiducial region. The result is consistent with the NLO SM prediction.

[5] KHACHATRYAN 16AD based on 19.5 fb^{-1} of data. The lepton charge asymmetry is measured as $A_C^{\ell\ell} = 0.003 \pm 0.006 \pm 0.003$. All the measurements are consistent with the SM predictions.

[6] KHACHATRYAN 16AH based on 19.6 fb^{-1} of data. The same data set as in KHACHATRYAN 16T is used. A template technique is used, which is sensitive to the charge anti-symmetric component of the $t\bar{t}$ rapidity distributions and statistically advantageous. The result is consistent with the SM predictions.

[7] KHACHATRYAN 16T based on 19.7 fb^{-1} of data. The same data set as in KHACHATRYAN 16AH is used. After kinematic reconstruction the top quark momenta are corrected for detector resolution and acceptance effects by unfolding, using parton level information of the MC generators. All the measurements are consistent with the SM predictions.

This result together with the helicity polarization is shown in a 2-dimensional plot in Fig.4. These results are consistent with the SM prediction.

[2] ABAZOV 17 based on 9.7 fb^{-1} of data. The value is top quark polarization times spin analyzing power in the helicity basis. The result is consistent with the SM prediction. This result together with the beam polarization is shown in a 2-dimensional plot in Fig.4.

[3] ABAZOV 17 based on 9.7 fb^{-1} of data. The value is top quark polarization times spin analyzing power in the transverse basis. The result is consistent with the SM prediction.

[4] ABAZOV 15K based on 9.7 fb^{-1} of data. The value is top quark polarization times spin analyzing power in the beam basis. The result is consistent with the SM prediction of -0.0019 ± 0.0005.

t-quark Polarization in $t\bar{t}$ Events in pp Collisions at $\sqrt{s} = 7$ TeV

The double differential distribution in polar angles, θ_1 (θ_2) of the decay particle of the top (anti-top) decay products, is parametrized as $(1/\sigma)d\sigma/(d\cos\theta_1\, d\cos\theta_2) = (1/4)\,(\,1 + A_t\cos\theta_1 + A_{\bar{t}}\cos\theta_2 - C\cos\theta_1\cos\theta_2\,)$. The charged lepton is used to tag t or $\bar{t}$. The coefficient A_t and $A_{\bar{t}}$ measure the average helicity of t and $\bar{t}$, respectively. $A_{CPC} = A_t = A_{\bar{t}}$ assumes CP conservation, whereas $A_{CPV} = A_t = -A_{\bar{t}}$ corresponds to maximal CP violation.

[1] AABOUD 17BB based on 20.2 fb^{-1} of pp data. Triple-differential decay rate of top quark is used to simultaneously determine five generalized Wtb couplings as well as the top polarization. α_ℓ denotes the spin analyzing power of charged lepton, and the spin axis of the top polarization P is taken along the spectator-quark momentum in the top rest frame. The value is compatible with the SM prediction of about 0.9.

[2] AABOUD 17I based on 20.2 fb^{-1} of pp data. A cut-based analysis is used to discriminate between signal and backgrounds. α_ℓ denotes the spin analyzing power of charged lepton, and the spin axis of the top polarization P is taken along the spectator-quark momentum in the top rest frame. See this paper for a number of other asymmetries and measurements that are not included here.

[3] AABOUD 17I based on 20.2 fb^{-1} of pp data. A cut-based analysis is used to discriminate between signal and backgrounds. $F_\pm$ denotes W helicity fraction, and the spin axis of the top polarization P is taken along the spectator-quark momentum in the top rest frame. See this paper for a number of other asymmetries and measurements that are not included here.

[4] KHACHATRYAN 16BO based on 19.7 fb^{-1} of data. A high-purity sample with a muon is selected by a multivariate analysis. The value is the top spin asymmetry, given by one half of the spin analyzing power α_μ (=1 at LO of SM) times the top polarization, P, where the spin axis is defined as the direction of the untagged jet in the top rest frame. The value is compatible with the SM prediction of 0.44 with a 2.0σ deviation.

t-quark Polarization in Single Top Events in pp Collisions at $\sqrt{s}$ = 13 TeV

0.440 ± 0.070	[2] SIRUNYAN	20R	CMS	$(\alpha_\ell P)/2$; t-channel

[1] AAD 22Z based on 139 fb^{-1} of data. Three components of t or $\overline{t}$ polarization vector (defined in the t or $\overline{t}$ rest frame) are measured in t-channel single top production using ℓ momentum distribution in the $\ell + \not{E}_T$ + 2j (with 1 of them b-jet) channel. The measured values are in agreement with NNLO SM prediction. Constraints on the Wilson coefficients of SMEFT are obtained as $-0.9 < C_{tW} < 1.4$ and $-0.8 < C_{itW} < 0.2$.

[2] SIRUNYAN 20R based on 36.1 fb^{-1} of data. Differential cross sections for t-channel single top production are measured using 1ℓ + 2,3-jet mode and found to be in good agreement with SM predictions. The value is the top spin asymmetry, given by 1/2 of the spin analyzing power α_ℓ (=1 at LO of SM) times the top polarization P, where the spin axis is defined as the direction of the spectator quark in the top rest frame at the parton level. It is in good agreement with the NLO SM prediction of 0.436.

$gg \to t\overline{t}$ Fraction in $p\overline{p}$ Collisions at $\sqrt{s}$ = 1.96 TeV

VALUE	CL%	DOCUMENT ID		TECN	COMMENT
• • • We do not use the following data for averages, fits, limits, etc. • • •					
<0.33	68	[1] AALTONEN	09F	CDF	$t\overline{t}$ correlations
0.07 ± 0.14 ± 0.07		[2] AALTONEN	08AG	CDF	low p_T number of tracks

[1] Based on 955 pb^{-1}. AALTONEN 09F used differences in the $t\overline{t}$ production angular distribution and polarization correlation to descriminate between $gg \to t\overline{t}$ and $q\overline{q} \to t\overline{t}$ subprocesses. The combination with the result of AALTONEN 08AG gives $0.07^{+0.15}_{-0.07}$.

[2] Result is based on 0.96 fb^{-1} of data. The contribution of the subprocesses $gg \to t\overline{t}$ and $q\overline{q} \to t\overline{t}$ is distinguished by using the difference between quark and gluon initiated jets in the number of small p_T (0.3 GeV < p_T < 3 GeV) charged particles in the central region ($|\eta| < 1.1$).

A_{FB} of $t\overline{t}$ in $p\overline{p}$ Collisions at $\sqrt{s}$ = 1.96 TeV

A_{FB} = Forward-backward asymmetry.

[1] AALTONEN 18 based on 9–10 fb^{-1} of $p\overline{p}$ data at $\sqrt{s}$ = 1.96 TeV. The value is the asymmetry in the number of reconstructed $t\overline{t}$ events with rapidity $y_t > y_{\overline{t}}$ and those with $y_t < y_{\overline{t}}$. The combined fits to CDF and D0 single lepton and $\ell\ell$ asymmetries give $A^\ell_{FB} = 0.073 \pm 0.016 \pm 0.012$ and $A^{\ell\ell}_{FB} = 0.108 \pm 0.043 \pm 0.016$, respectively. The results are consistent with the SM predictions.

[2] ABAZOV 15K based on 9.7 fb^{-1} of data. The result is consistent with the SM predictions. By combining with the previous D0 measurement in the ℓ + jet channel ABAZOV 14H, $A^\ell_{FB} = 0.118 \pm 0.025 \pm 0.013$ is obtained.

[3] AALTONEN 14F based on 9.1 fb^{-1} of data. A^ℓ_{FB} and $A^{\ell\ell}_{FB}$ denote, respectively, the asymmetries $(N(x>0) - N(x<0))/N_{tot}$ for $x = q_\ell \eta_\ell$ (q_ℓ is the charge of ℓ) and $x = \eta_{\ell^+} - \eta_{\ell^-}$. Both results are consistent with the SM predictions. By combining with the previous CDF measurement in the ℓ+jet channel AALTONEN 13X, $A^\ell_{FB} = 0.098^{+0.028}_{-0.026}$ is obtained. The combined result is about two sigma larger than the SM prediction of $A^\ell_{FB} = 0.038 \pm 0.003$.

[4] Based on 9.7 fb^{-1} of $p\overline{p}$ data at $\sqrt{s}$ = 1.96 TeV. The asymmetry is corrected for the production level for events with $|y_l| < 1.5$. Asymmetry as functions of $E_T(\ell)$ and $|y_l|$ are given in Figs. 7 and 8, respectively. Combination with the asymmetry measured in the dilepton channel [ABAZOV 13P] gives $A^\ell_{FB} = 4.2 \pm 2.0 \pm 1.4$ %, in agreement with the SM prediction of 2.0%.

[5] Based on 9.7 fb^{-1} of data of $p\overline{p}$ data at $\sqrt{s}$=1.96 TeV. The measured asymmetry is in agreement with the SM predictions of 8.8 ± 0.9 % [BERNREUTHER 12], which includes the EW effects. The dependences of the asymmetry on $|y(t) - y(\overline{t})|$ and $m_{t\overline{t}}$ are shown in Figs. 9 and 10, respectively.

[6] Based on 9.4 fb^{-1} of data. Reported A_{FB} values come from the determination of a_i coefficients of $d\sigma/d(\cos\theta_t) = \Sigma_i\ a_i P_i(\cos(\theta_t))$ measurement. The result of $a_1/a_0 = (40 \pm 12)$% seems higher than the NLO SM prediction of (15^{+7}_{-3})%.

[7] Based on 9.4 fb^{-1} of data. The quoted result is the asymmetry at the parton level.

[8] Based on 9.4 fb^{-1} of data. The observed asymmetry is to be compared with the SM prediction of $A^\ell_{FB} = 0.038 \pm 0.003$.

[9] Based on 5.4 fb^{-1} of data. ABAZOV 13A studied the dilepton channel of the $t\overline{t}$ events and measured the leptonic forward-backward asymmetry to be $A^\ell_{FB} = 5.8 \pm 5.1 \pm 1.3$%, which is consistent with the SM (QCD+EW) prediction of 4.7 ± 0.1%. The result is obtained after combining the measurement (15.2 ± 4.0%) in the ℓ + jets channel ABAZOV 11AH. The top quark helicity is measured by using the neutrino weighting method to be consistent with zero in both dilepton and ℓ + jets channels.

[10] Based on 5.3 fb^{-1} of data. The error is statistical and systematic combined. Events with lepton + $\not{E}_T$ + ≥ 4jets(≥ 1b) are used. AALTONEN 11F also measures the asymmetry as a function of the rapidity difference $|y_t - y_{\overline{t}}|$. The NLO QCD predictions [MCFM] are (4.0 ± 0.6)% and (8.8 ± 1.3)% for $m_{t\overline{t}}$ < 450 and > 450 GeV, respectively.

[11] Based on 5.4 fb^{-1} of data. The error is statistical and systematic combined. The quoted asymmetry is obtained after unfolding to be compared with the MC@NLO prediction of (5.0 ± 0.1)%. No significant difference between the $m_{t\overline{t}}$ < 450 and > 450 GeV data samples is found. A corrected asymmetry based on the lepton from a top quark decay of (15.2 ± 4.0)% is measured to be compared to the MC@NLO prediction of (2.1 ± 0.1)%.

[12] Result is based on 1.9 fb^{-1} of data. The FB asymmetry in the $t\overline{t}$ events has been measured in the ℓ + jets mode, where the lepton charge is used as the flavor tag. The asymmetry in the $p\overline{p}$ frame is defined in terms of cos(θ) of hadronically decaying t-quark momentum, whereas that in the $t\overline{t}$ frame is defined in terms of the t and $\overline{t}$ rapidity difference. The results are consistent (≤ 2 σ) with the SM predictions.

[13] Result is based on 0.9 fb^{-1} of data. The asymmetry in the number of $t\overline{t}$ events with $y_t > y_{\overline{t}}$ and those with $y_t < y_{\overline{t}}$ has been measured in the lepton + jets final state. The observed value is consistent with the SM prediction of 0.8% by MC@NLO, and an upper bound on the $Z' \to t\overline{t}$ contribution for the SM Z-like couplings is given in in Fig. 2 for 350 GeV < $m_{Z'}$ < 1 TeV.

t-Quark Electric Charge

	[5] ABAZOV	07C	D0	fraction of |q|=4e/3 pair

[1] AAD 13AY result is based on 2.05 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV, the result is obtained by reconstructing $t\overline{t}$ events in the lepton + jets final state, where b-jet charges are tagged by the jet-charge algorithm. This measurement excludes the charge $-4/3$ assignment to the top quark at more than 8 standard deviations.

[2] ABAZOV 14D result is based on 5.3 fb^{-1} of $p\overline{p}$ data at $\sqrt{s}$=1.96 TeV. The electric charge of $b + W$ system in $t\overline{t}$ candidate events is measured from the charges of the leptons from W decay and in b jets. Under the assumption that the $b + W$ system consists of the sum of the top quark and the charge $-4/3$ quark b'(-4/3) of the same mass, the top quark fraction is found to be $f = 0.88 \pm 0.13$ (stat) ± 0.11 (syst), or the upper bound for the b'(-4/3) contamination of $1 - f < 0.46$ (95% CL).

[3] AALTONEN 13J excludes the charge $-4/3$ assignment to the top quark at 99% CL, using 5.6 fb^{-1} of data in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. Result is obtained by reconstructing $t\overline{t}$ events in the lepton + jets final state, where b-jet charges are tagged by the jet-charge algorithm.

[4] AALTONEN 10S excludes the charge $-4/3$ assignment for the top quark [CHANG 99] at 95%CL, using 2.7 fb^{-1} of data in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. Result is obtained by reconstructing $t\overline{t}$ events in the lepton + jets final state, where b-jet charges are tagged by the SLT (soft lepton tag) algorithm.

[5] ABAZOV 07C reports an upper limit $\rho < 0.80$ (90% CL) on the fraction ρ of exotic quark pairs $Q\overline{Q}$ with electric charge $|q| = 4e/3$ in $t\overline{t}$ candidate events with high p_T lepton, missing E_T and ≥ 4 jets. The result is obtained by measuring the fraction of

events in which the quark pair decays into $W^- + b$ and $W^+ + \overline{b}$, where b and $\overline{b}$ jets are discriminated by using the charge and momenta of tracks within the jet cones. The maximum CL at which the model of CHANG 99 can be excluded is 92%. Based on 370 pb^{-1} of data at $\sqrt{s} = 1.96$ TeV.

[1] AAD 23AV based on 139 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. Pair production of vector-like b' is searched for in the mode $\ell^{\pm}\ell^{\mp}$ + ≥ 2j (≥ 1b-tagged) + $\not{E}_T$ or with 3ℓ. The data are consistent with the SM background predictions and limits are obtained for different branching ratios.

[2] TUMASYAN 23V based on 138 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. Pair production of vector-like b' is seached for in the single-lepton, same-sign charge dilepton and multi-lepton channels. The data are consistent with the SM background predictions and limits are obtained for different branching ratios.

[3] SIRUNYAN 20BI based on 137 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. Pair production of vector-like b' is seached for with each b' decaying into Zb or hb. Analysis focuses on final states consisting of jets from six quarks. Mass limits are obtained for a variety of branching ratios of b' decays.

[4] AABOUD 18CE based on 36.1 fb^{-1} of proton-proton data taken at $\sqrt{s}$ = 13 TeV. Events including a same-sign lepton pair are used. The limit is for a singlet model, assuming the branching ratios of b' into Zb, Wt and Hb as predicted by the model.

[5] AABOUD 18CL, AABOUD 18CP based on 36.1 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. The limit is for the pair-produced vector-like b' using all-hadronic final state. The analysis is particularly powerful for the $b' \to hb$ mode. Assuming the pure decay only in this mode sets a limit $m_{b'} > 1010$ GeV.

[6] AABOUD 18CP based on 36.1 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. Pair and single production of vector-like b' are seached for with at least one b' decaying into Zb. In the case of $B(b' \to Zb) = 1$, the limit is $m_{b'} > 1220$ GeV.

[7] The limit is for the singlet model, assuming that the branching ratios into Wt, Zb, hb add up to one.

[8] The limit is for the doublet model, assuming that the branching ratios into Wt, Zb, hb add up to one.

[9] AABOUD 18CR based on 36.1 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. A combination of searches for the pair-produced vector-like b' in various decay channels ($b' \to Wt$, Zb, hb). Also a model-independent limit is obtained as $m_{b'} > 1.03$ TeV, assuming that the branching ratios into Zb, Wt, and hb add up to one.

[10] The limit is for the singlet b'.

[11] The limit is for b' in a weak isospin doublet (t',b') and $|V_{t'b}| \ll |V_{tb'}|$. For a b' in a doublet with a charge $-4/3$ vector-like quark, the limit $m_{b'} > 1.14$ TeV is obtained.

[12] SIRUNYAN 18Q based on 19.7 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. The limit is for the pair-produced vector-like b' that couple only to light quarks. Upper cross section limits on the single production of a b' and constraints for other decay channels (Zq and Hq) are also given in the paper.

[13] SIRUNYAN 17AU based on 2.3–2.6 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. Limit on pair-produced singlet vector-like b' using one lepton and several jets. The mass bound is given for a b' transforming as a singlet under the electroweak symmetry group, assumed to decay through W, Z or Higgs boson (which decays to jets) and to a third generation quark.

[14] AAD 15Z based on 20.3 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. Used events with ℓ + $\not{E}_T$ + ≥ 6j (≥ 1 b) and at least one pair of jets from weak boson decay, primarily designed to select the signature $b'\overline{b}' \to WWt\overline{t} \to WWWWb\overline{b}$. This is a limit on pair-produced vector-like b'. The lower mass limit is 640 GeV for a vector-like singlet b'.

[15] Result is based on 1.1 fb^{-1} of data. No signal is found for the search of long-lived particles which decay into final states with two electrons or photons, and upper bound on the cross section times branching fraction is obtained for 2 < cτ< 7000 mm; see Fig. 3. 95% CL excluded region of b' lifetime and mass is shown in Fig. 4.

[16] ACOSTA 03 looked for long-lived fourth generation quarks in the data sample of 90 pb^{-1} of $\sqrt{s}$=1.8 TeV $p\overline{p}$ collisions by using the muon-like penetration and anomalously high ionization energy loss signature. The corresponding lower mass bound for the charge (2/3)e quark (t') is 220 GeV. The t' bound is higher than the b' bound because t' is more likely to produce charged hadrons than b'. The 95% CL upper bounds for the production cross sections are given in their Fig. 3.

[17] AAD 23AG based on 139 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. Pair production of vector-like top or bs is searched for in the mode 1ℓ + ≥ 4j(≥ 1b-tagged) + $\not{E}_T$. The data are consistent with the SM background predictions and limits are obtained for different branching ratios. Masses below 1.59 TeV are excluded assuming a mass-degenerate vector-like doublet (t',b') model.

[18] SIRUNYAN 19AQ based on 35.9 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. Pair production of vector-like b' is seached for with one b' decaying into Zb and the other b' decaying into Wt, Zb, hb. Events with an opposite-sign lepton pair consistent with coming from Z and jets are used. Mass limits are obtained for a variety of branching ratios of b'.

[19] SIRUNYAN 19BW based on 35.9 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. The limit is for the pair-produced vector-like b' using all-hadronic final state. The analysis is made for the Zb, Wt, hb modes and mass limits are obtained for a variety of branching ratios.

[20] AABOUD 18AW based on 36.1 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. The limit is for the pair-produced vector-like b' using lepton-plus-jets final state. The search is also sensitive to the decays into Zb and Hb final states.

[21] SIRUNYAN 18BM based on 35.9 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. The limit is for the pair-produced vector-like b'. Three channels (single lepton, same-charge 2 leptons, or at least 3 leptons) are considered for various branching fraction combinations. Assuming $B(tW) = 1$, the limit is 1240 GeV and for $B(bZ) = 1$ it is 960 GeV.

[22] KHACHATRYAN 16AN based on 19.7 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. Limit on pair-produced vector-like b' using 1, 2, and >2 leptons as well as fully hadronic final states. Other limits depending on the branching fractions to tW, bZ, and bH are given in Table IX.

[23] AAD 15AR based on 20.3 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. Used lepton-plus-jets final state. See Fig. 24 for mass limits in the plane of $B(b' \to Wt)$ vs. $B(b' \to Hb)$ from $b'\overline{b}' \to Hb$ + X searches.

[24] AAD 15BY based on 20.3 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. Limit on pair-produced vector-like b' assuming the branching fractions to W, Z, and h modes of the singlet model. Used events containing ≥ 2ℓ + $\not{E}_T$ + ≥ 2j (≥ 1 b) and including a same-sign lepton pair.

[25] AAD 15BY based on 20.3 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. Limit on pair-produced chiral b'-quark. Used events containing ≥ 2ℓ + $\not{E}_T$ + ≥ 2j (≥ 1 b) and including a same-sign lepton pair.

[26] AAD 15CN based on 20.3 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. Limit on pair-production of chiral b'-quark. Used events with ℓ + $\not{E}_T$ + ≥ 4j (non-b-tagged). Limits on a heavy vector-like quark, which decays into Wq, Zq, hq, are presented in the plane $B(Q \to Wq)$ vs. $B(Q \to hq)$ in Fig. 12.

[27] Based on 20.3 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. No significant excess over SM expectation is found in the search for pair production or single production of b' in the events with dilepton from a high p_T Z and additional jets (≥ 1 b-tag). If instead of $B(b' \to Wt) = 1$ an electroweak singlet with $B(b' \to Wt) \sim 0.45$ is assumed, the limit reduces to 685 GeV.

[28] Based on 5.0 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV. CHATRCHYAN 13I looked for events with one isolated electron or muon, large $\not{E}_T$, and at least four jets with large transverse momenta, where one jet is likely to originate from the decay of a bottom quark.

[29] Based on 1.04 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV. No signal is found for the search of heavy quark pair production that decay into W and a t quark in the events with a high p_T isolated lepton, large $\not{E}_T$, and at least 6 jets in which one, two or more dijets are from W.

[30] Based on 2.0 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV. No $b' \to Zb$ invariant mass peak is found in the search of heavy quark pair production that decay into Z and a b quark in events with $Z \to e^+e^-$ and at least one b-jet. The lower mass limit is 358 GeV for a vector-like singlet b' mixing solely with the third SM generation.

[31] Based on 1.04 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV. No signal is found for the search of heavy quark pair production that decay into W and a quark in the events with dileptons, large $\not{E}_T$, and ≥ 2 jets.

[32] Based on 1.04 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV. AAD 12BE looked for events with two isolated like-sign leptons and at least 2 jets, large $\not{E}_T$ and H_T > 350 GeV.

[33] Based on 5 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV. CHATRCHYAN 12BH searched for QCD and EW production of single and pair of degenerate 4'th generation quarks that decay to bW or tW. Absence of signal in events with one lepton, same-sign dileptons or tri-leptons gives the bound. With a mass difference of 25 GeV/c^2 between $m_{t'}$ and $m_{b'}$, the corresponding limit shifts by about ±20 GeV/c^2.

[34] Based on 4.9 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV. CHATRCHYAN 12X looked for events with trileptons or same-sign dileptons and at least one b jet.

[35] Based on 4.8 fb^{-1} of data in $p\overline{p}$ collisions at 1.96 TeV. AALTONEN 11J looked for events with ℓ + $\not{E}_T$ + ≥ 5j (≥ 1 b or c). No signal is observed and the bound $\sigma(b'\overline{b}')$ < 30 fb for $m_{b'} > 375$ GeV is found for $B(b' \to Wt) = 1$.

[36] Based on 34 pb^{-1} of data in pp collisions at 7 TeV. CHATRCHYAN 11L looked for multi-jet events with trileptons or same-sign dileptons. No excess above the SM background excludes $m_{b'}$ between 255 and 361 GeV at 95% CL for $B(b' \to Wt) = 1$.

[37] Based on 2.7 fb^{-1} of data in $p\overline{p}$ collisions at $\sqrt{s}$ = 1.96 TeV. AALTONEN 10H looked for pair production of heavy quarks which decay into tW^- or tW^+, in events with same sign dileptons (e or μ), several jets and large missing E_T. The result is obtained for b' which decays into tW^-. For the charge 5/3 quark ($T_{5/3}$) which decays into tW^+, $m_{T_{5/3}} > 365$ GeV (95% CL) is found when it has the charge $-1/3$ partner B of the same mass.

[38] FLACCO 10 result is obtained from AALTONEN 10H result of $m_{b'} > 338$ GeV, by relaxing the condition $B(b' \to Wt) = 100\%$ when $m_{b'} > m_{t'}$.

[39] Result is based on 1.06 fb^{-1} of data. No excess from the SM Z+jet events is found when Z decays into ee or $\mu\mu$. The $m_{b'}$ bound is found by comparing the resulting upper

bound on $\sigma(b'\overline{b}')$ [1-(1-B($b' \to Z\,b$))^2] and the LO estimate of the b' pair production cross section shown in Fig. 38 of the article.

[40] HUANG 08 reexamined the b' mass lower bound of 268 GeV obtained in AALTONEN 07C that assumes B($b' \to Z\,b$) = 1, which does not hold for $m_{b'} > 255$ GeV. The lower mass bound is given in the plane of $\sin^2(\theta_{t\,b'})$ and $m_{b'}$.

[41] AFFOLDER 00 looked for b' that decays in to b+Z. The signal searched for is $bbZZ$ events where one Z decays into e^+e^- or $\mu^+\mu^-$ and the other Z decays hadronically. The bound assumes B($b' \to Z\,b$)= 100%. Between 100 GeV and 199 GeV, the 95%CL upper bound on $\sigma(b' \to \overline{b}')\times$B$^2(b' \to Z\,b)$ is also given (see their Fig. 2).

[42] ABE 98N looked for $Z \to e^+e^-$ decays with displaced vertices. Quoted limit assumes B($b' \to Z\,b$)=1 and $c\tau_{b'}$=1 cm. The limit is lower than $m_Z + m_b$ ($\sim$ 96 GeV) if $c\tau >$ 22 cm or $c\tau <$ 0.009 cm. See their Fig. 4.

[43] ABACHI 97D searched for b' that decays mainly via FCNC. They obtained 95%CL upper bounds on B($b'\overline{b}' \to \gamma$+ 3 jets) and B($b'\overline{b}' \to 2\gamma$+ 2 jets), which can be interpreted as the lower mass bound $m_{b'} > m_Z + m_b$.

[44] ABACHI 95F bound on the top-quark also applies to b' and t' quarks that decay predominantly into W. See FROGGATT 97.

[45] MUKHOPADHYAYA 93 analyze CDF dilepton data of ABE 92G in terms of a new quark decaying via flavor-changing neutral current. The above limit assumes B($b' \to b\ell^+\ell^-$)=1%. For an exotic quark decaying only via virtual Z [B($b\ell^+\ell^-$) = 3%], the limit is 85 GeV.

[46] ABE 92 dilepton analysis limit of >85 GeV at CL=95% also applies to b' quarks, as discussed in ABE 90B.

[47] ABE 90B exclude the region 28–72 GeV.

[48] AKESSON 90 searched for events having an electron with $p_T > 12$ GeV, missing momentum > 15 GeV, and a jet with $E_T > 10$ GeV, $|\eta| < 2.2$, and excluded $m_{b'}$ between 30 and 69 GeV.

[49] For the reduction of the limit due to non-charged-current decay modes, see Fig. 19 of ALBAJAR 90B.

[50] ALBAJAR 88 study events at $E_{cm} = 546$ and 630 GeV with a muon or isolated electron, accompanied by one or more jets and find agreement with Monte Carlo predictions for the production of charm and bottom, without the need for a new quark. The lower mass limit is obtained by using a conservative estimate for the $b'\overline{b}'$ production cross section and by assuming that it cannot be produced in W decays. The value quoted here is revised using the full $O(\alpha_s^3)$ cross section of ALTARELLI 88.

$b'(-1/3)$ mass limits from single production in $p\overline{p}$ and pp collisions

[1] TUMASYAN 22O based on 138 fb^{-1} of data in pp collisions at 13 TeV. No significant excess over SM expectation is found in the search for a left-handed b' assuming 100% decay to tW using a t-tagged jet and a lepton from W. The model assumes that the b' has the excited quark couplings. The bound is from a statistical combination with an earlier analysis by SIRUNYAN 21AG. The 95% CL bounds are also set as 3.0, 3.0, and 3.2 TeV, respectively, for left-handed, right-handed, and vector-like couplings.

[2] ABAZOV 11F based on 5.4 fb^{-1} of data in ppbar collisions at 1.96 TeV. ABAZOV 11F looked for single production of b' via the W or Z coupling to the first generation up or down quarks, respectively. Model independent cross section limits for the single production processes $p\overline{p} \to b'q \to Wuq$, and $p\overline{p} \to b'q \to Zdq$ are given in Figs. 3 and 4, respectively, and the mass limits are obtained for the model of ATRE 09 with degenerate bi-doublets of vector-like quarks.

[3] AAD 23CQ based on 139 fb^{-1} of data in pp collisions at 13 TeV. No significant excess over SM expectation is found. Limits on mass and production cross section of a vector-like b' are obtained in several theoretical scenarios determined by the couplings betwen b' and W, Z, h.

[4] SIRUNYAN 21AG based on 137 fb^{-1} of data in pp collisions at 13 TeV. No significant excess over SM expectation is found in the search for a left-handed b' assuming 100% decay to tW using all hadronic final states, where t and W are tagged as single jets, respectively. The model assumes that the b' has the excited quark couplings. The 95% CL bounds are also set as 2.8 and 3.1 TeV, respectively, for the right-handed and vector-like couplings.

[5] SIRUNYAN 19AI based on 35.9 fb^{-1} of pp data at $\sqrt{s} = 13$ TeV. Exclusion limits are set on the product of the production cross section and branching fraction for the $b'(-1/3) + b$ and $b'(-1/3) + t$ modes as a function of the vector-like quark mass in Figs. 7 and 8 and in Tab. 2 for relative vector-like quark widths between 1 and 30% for left- and right-handed vector-like quark couplings. No significant deviation from the SM prediction is observed.

[6] AAD 16AH based on 20.3 fb^{-1} of data in pp collisions at 8 TeV. No significant excess over SM expectation is found in the search for a vector-like b' in the single-lepton and dilepton channels (ℓ or $\ell\ell$) + 1,2,3 j ($\geq 1b$). The model assumes that the b' has the excited quark couplings.

[7] Based on 19.7 fb^{-1} of data in pp collisions at 8 TeV. Limit on left-handed b' assuming 100% decay to tW and using all-hadronic, lepton + jets, and dilepton final states.

[8] Based on 19.7 fb^{-1} of data in pp collisions at 8 TeV. Limit on right-handed b' assuming 100% decay to tW and using all-hadronic, lepton + jets, and dilepton final states.

[9] Based on 19.7 fb^{-1} of data in pp collisions at 8 TeV. Limit on vector-like b' assuming 100% decay to tW and using all-hadronic, lepton+jets, and dilepton final states.

MASS LIMITS for b' (4th Generation) Quark or Hadron in e^+e^- Collisions

Search for hadrons containing a fourth-generation $-1/3$ quark denoted b'.

The last column specifies the assumption for the decay mode (CC denotes the conventional charged-current decay) and the event signature which is looked for.

[1] DECAMP 90F looked for isolated charged particles, for isolated photons, and for four-jet final states. The modes $b' \to bg$ for B($b' \to bg$) > 65% $b' \to b\gamma$ for B($b' \to b\gamma$) > 5% are excluded. Charged Higgs decay were not discussed.

[2] ABDALLAH 07 searched for b' pair production at E_{cm}=196–209 GeV, with 420 pb^{-1}. No signal leads to the 95% CL upper limits on B($b' \to bZ$) and B($b' \to cW$) for $m_{b'}$ = 96 to 103 GeV.

[3] ADRIANI 93G search for vector quarkonium states near Z and give limit on quarkonium–Z mixing parameter $\delta m^2 <$(10–30) GeV^2 (95%CL) for the mass 88–94.5 GeV. Using Richardson potential, a 1S ($b'\overline{b}'$) state is excluded for the mass range 87.7–94.7 GeV. This range depends on the potential choice.

[4] ABREU 90D assumed $m_{H^-} < m_{b'} - 3$ GeV.

[5] Superseded by ABREU 91F.

[6] AKRAWY 90B search was restricted to data near the Z peak at $E_{cm} = 91.26$ GeV at LEP. The excluded region is between 23.6 and 41.4 GeV if no H^+ decays exist. For charged Higgs decays the excluded regions are between (m_{H^+} + 1.5 GeV) and 45.5 GeV.

[7] AKRAWY 90J search for isolated photons in hadronic Z decay and derive B($Z \to b'\overline{b}'$)·B($b' \to \gamma$X)/B($Z \to$ hadrons) < 2.2×10^{-3}. Mass limit assumes B($b' \to \gamma$X) > 10%.

[8] ABE 89E search at E_{cm} = 56–57 GeV at TRISTAN for multihadron events with a spherical shape (using thrust and acoplanarity) or containing isolated leptons.

[9] ABE 89G search was at E_{cm} = 55–60.8 GeV at TRISTAN.

[10] If the photonic decay mode is large (B($b' \to b\gamma$) > 25%), the ABRAMS 89C limit is 45.4 GeV. The limit for for Higgs decay ($b' \to cH^-$, $H^- \to \overline{\tau}s$) is 45.2 GeV.

[11] ADACHI 89C search was at E_{cm} = 56.5–60.8 GeV at TRISTAN using multi-hadron events accompanying muons.

[12] ADACHI 89C also gives limits for any mixture of CC and bg decays.

[13] ENO 89 search at E_{cm} = 50–60.8 at TRISTAN.

[14] ENO 89 considers arbitrary mixture of the charged current, bg, and $b\gamma$ decays.

[15] IGARASHI 88 searches for leptons in low-thrust events and gives $\Delta R(b') < 0.26$ (95% CL) assuming charged current decay, which translates to $m_{b'} > 24.4$ GeV.

[16] SAGAWA 88 set limit σ(top) < 6.1 pb at CL=95% for top-flavored hadron production from event shape analyses at E_{cm} = 52 GeV. By using the quark parton model cross-section formula near threshold, the above limit leads to lower mass bounds of 23.8 GeV for charge $-1/3$ quarks.

[17] ADEVA 86 give 95%CL upper bound on an excess of the normalized cross section, ΔR, as a function of the minimum c.m. energy (see their figure 3). Production of a pair of 1/3 charge quarks is excluded up to E_{cm} = 45.4 GeV.

[18] ALTHOFF 84C narrow state search sets limit $\Gamma(e^+e^-)$B(hadrons) <2.4 keV CL = 95% and heavy charge 1/3 quark pair production $m >$21 GeV, CL = 95%.

[19] ALTHOFF 84I exclude heavy quark pair production for 7 <m <19 GeV (1/3 charge) using aplanarity distributions (CL = 95%).

[1] AAD 23AV based on 139 fb^{-1} of pp data at $\sqrt{s} = 13$ TeV. Pair production of vector-like t' is searched for in the mode $\ell^{\pm}\ell^{\mp} + \geq 2$j (≥ 1b-tagged) + $\not{E}_T$ or with 3ℓ. The data are consistent with the SM background predictions and limits are obtained for different branching ratios.

[2] TUMASYAN 23AX based on 138 fb^{-1} of pp data at $\sqrt{s} = 13$ TeV. A vector-like t' is seached for in the $t + H$ ($H \to \gamma\gamma$) decay channel. EW production via a coupling to third-generation quarks of $\kappa_T = 0.25$ is assumed. The branching fractions are assumed to be 50, 25, and 25%, respectively, for bW, tZ, and tH decays.

[3] TUMASYAN 23V based on 138 fb^{-1} of pp data at $\sqrt{s} = 13$ TeV. Pair production of vector-like t' is seached for in the single-lepton, same-sign charge dilepton and multi-lepton channels. The data are consistent with the SM background predictions and limits are obtained for different branching ratios. Masses below 1.48 TeV are excluded for all decays to third generation quarks.

[4] AABOUD 18CE based on 36.1 fb^{-1} of proton-proton data taken at $\sqrt{s} = 13$ TeV. Events including a same-sign lepton pair are used. The limit is for a singlet model, assuming the branching ratios of t' into Zt, Wb and Ht as predicted by the model.

[5] AABOUD 18CP based on 36.1 fb^{-1} of pp data at $\sqrt{s} = 13$ TeV. Pair and single production of vector-like t' are seached for with at least one t' decaying into Zt. In the case of $B(t' \to Zt) = 1$, the limit is $m_{t'} > 1340$ GeV.

[6] The limit is for the singlet model, assuming that the branching ratios into Zt, Wb, and Ht add up to one.

[7] The limit is for the doublet model, assuming that the branching ratios into Zt, Wb, and Ht add up to one.

[8] AABOUD 18CR based on 36.1 fb^{-1} of pp data at $\sqrt{s} = 13$ TeV. A combination of searches for the pair-produced vector-like t' in various decay channels ($t' \to Wb$, Zt, ht). Also a model-independent limit is obtained as $m_{t'} > 1.31$ TeV, assuming that the branching ratios into Zt, Wb and ht add up to one.

[9] The limit is for the singlet t'.

[10] The limit is for t' in a weak isospin doublet (t',b') and $|V_{t'b}| \ll |V_{tb'}|$.

[11] SIRUNYAN 18BM based on 35.9 fb^{-1} of pp data at $\sqrt{s} = 13$ TeV. The limit is for the pair-produced vector-like t'. Three channels (single lepton, same-charge 2 leptons, or at least 3 leptons) are considered for various branching fraction combinations. Assuming $B(tH) = 1$, the limit is 1270 GeV and for $B(tZ) = 1$ it is 1300 GeV.

[12] SIRUNYAN 18Q based on 19.7 fb^{-1} of pp data at $\sqrt{s} = 8$ TeV. The limit is for the pair-produced vector-like t' that couple only to light quarks. Constraints for other decay channels (Zq and Hq) are also given in the paper.

[13] SIRUNYAN 18W based on 35.8 fb^{-1} of pp data at $\sqrt{s} = 13$ TeV. The limit is for the vector-like t' pair-produced by strong interaction using lepton-plus-jets mode and assuming that $B(t' \to Wb)$ is 100product of the production cross section and branching faction to Wb for any new pair-produced heavy quark decaying to this channel as a narrow resonance.

[14] SIRUNYAN 17AU based on 2.3-2.6 fb^{-1} of pp data at $\sqrt{s} = 13$ TeV. Limit on pair-produced singlet vector-like t' using one lepton and several jets. The mass bound is given for a t' transforming as a singlet under the electroweak symmetry group, assumed to decay through W, Z or Higgs boson (which decays to jets) and to a third generation quark. For a doublet, the limit is >830 GeV. Other limits are also given in the paper.

[15] Based on 20.3 fb^{-1} of pp data at $\sqrt{s} = 8$ TeV. No significant excess over SM expectation is found in the search for pair production or single production of t' in the events with dilepton from a high p_T Z and additional jets (≥ 1 b-tag). If instead of $B(b' \to Wt) = 1$ an electroweak singlet with $B(b' \to Wt) \sim 0.45$ is assumed, the limit reduces to 685 GeV.

[16] Based on 1.04 fb^{-1} of pp data at $\sqrt{s} = 7$ TeV. No signal is found for the search of heavy quark pair production that decay into W and a quark in the events with dileptons, large $\not{E}_T$, and ≥ 2 jets.

[17] Based on 1.04 fb^{-1} of data in pp collisions at 7 TeV. AAD 12C looked for $t'\overline{t}'$ production followed by t' decaying into a top quark and X, an invisible particle, in a final state with an isolated high-P_T lepton, four or more jets, and a large missing transverse energy. No excess over the SM $t\overline{t}$ production gives the upper limit on $t'\overline{t}'$ production cross section as a function of $m_{t'}$ and m_X. The result is obtained for $B(t' \to Wt) = 1$.

[18] Based on 5 fb^{-1} of pp data at $\sqrt{s} = 7$ TeV. CHATRCHYAN 12BH searched for QCD and EW production of single and pair of degenerate 4'th generation quarks that decay to Wb or Wt. Absence of signal in events with one lepton, same-sign dileptons or tri-leptons gives the bound. With a mass difference of 25 GeV/c^2 between $m_{t'}$ and $m_{b'}$, the corresponding limit shifts by about $\pm$20 GeV/c^2.

[19] Based on 5.0 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV. CHATRCHYAN 12P looked for $t'\overline{t}'$ production events with two isolated high p_T leptons, large $\not{E}_T$, and 2 high p_T jets with b-tag. The absence of signal above the SM background gives the limit for B($t' \to Wb$) = 1.

[20] AAD 23AG based on 139 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. Pair production of vector-like top or bs is searched for in the mode $1\ell + \geq 4$j(≥ 1b-tagged) + $\not{E}_T$. The data are consistent with the SM background predictions and limits are obtained for different branching ratios. Masses below 1.59 TeV are excluded assuming a mass-degenerate vector-like doublet (t',b') model.

[21] SIRUNYAN 19AQ based on 35.9 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. Pair production of vector-like t' is seached for with one t' decaying into $Z\,t$ and the other t' decaying into Wb, $Z\,t$, $h\,t$. Events with an opposite-sign lepton pair consistent with coming from Z and jets are used. Mass limits are obtained for a variety of branching ratios of t'.

[22] SIRUNYAN 19BW based on 35.9 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. The limit is for the pair-produced vector-like t' using all-hadronic final state. The analysis is made for the Wb, $Z\,t$, $h\,t$ modes and mass limits are obtained for a variety of branching ratios.

[23] AABOUD 18CL based on 36.1 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. The limit is for the pair-produced vector-like t' using all-hadronic final state. The analysis is also made for the Wb, $Z\,t$, $h\,t$ modes and mass limits are obtained for a variety of branching ratios.

[24] AABOUD 17L based on 36.1 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. No signal is found in the search for heavy quark pair production that decay into $Z\,t$ followed by $Z \to \nu\nu$ in the events with one lepton, large $\not{E}_T$, and ≥ 4 jets. The lower mass limit 0.87 (1.05) TeV is obtained for the singlet (doublet) model with other possible decay modes.

[25] AAD 15AR based on 20.3 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. Used lepton-plus-jets final state. See Fig. 20 for mass limits in the plane of B($t' \to Ht$) vs. B($t' \to Wb$) from a combination of $t'\overline{t}' \to Wb + X$ and $t'\overline{t}' \to Ht + X$ searches. Any branching ratio scenario is excluded for mass below 715 GeV.

[26] AAD 15BY based on 20.3 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. Limit on pair-produced vector-like t' assuming the branching fractions to W, Z, and h modes of the singlet model. Used events containing $\geq 2\ell + \not{E}_T + \geq 2$j (≥ 1 b) and including a same-sign lepton pair.

[27] KHACHATRYAN 15AI based on 19.7 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. The search exploits all-hadronic final states by tagging boosted Higgs boson using jet substructure and b-tagging.

[28] Based on 19.5 fb^{-1} of pp data at $\sqrt{s}$ = 8TeV. The t' quark is pair produced and is assumed to decay into three different final states of bW, tZ, and th. The search is carried out using events with at least one isolated lepton.

[29] Based on 4.7 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV. No signal is found for the search of heavy quark pair production that decay into W and a b quark in the events with a high p_T isolated lepton, large $\not{E}_T$ and at least 3 jets ($\geq$ 1 b-tag). Vector-like quark of charge 2/3 with $400 < m_{t'} < 550$ GeV and B($t' \to Wb$) > 0.63 is excluded at 95% CL.

[30] Based on 5.0 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV. CHATRCHYAN 13I looked for events with one isolated electron or muon, large $\not{E}_T$, and at least four jets with large transverse momenta, where one jet is likely to originate from the decay of a bottom quark.

[31] Based on 1.04 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV. No signal is found in the search for pair produced heavy quarks that decay into W boson and a b quark in the events with a high p_T isolated lepton, large $\not{E}_T$ and at least 3 jets (≥ 1 b-tag).

[32] Based on 5.0 fb^{-1} of pp data at $\sqrt{s}$ = 7 TeV. CHATRCHYAN 12BC looked for $t'\overline{t}'$ production events with a single isolated high p_T lepton, large $\not{E}_T$ and at least 4 high p_T jets with a b-tag. The absence of signal above the SM background gives the limit for B($t' \to Wb$) = 1.

[33] Based on 5.7 fb^{-1} of data in $p\overline{p}$ collisions at 1.96 TeV. AALTONEN 11AH looked for $t'\overline{t}'$ production followed by t' decaying into a top quark and X, an invisible particle, in the all hadronic decay mode of $t\overline{t}$. No excess over the SM $t\overline{t}$ production gives the upper limit on $t'\overline{t}'$ production cross section as a function of $m_{t'}$ and m_X. The result is obtained for B($t' \to X\,t$) = 1.

[34] Based on 5.6 fb^{-1} of data in ppbar collisions at 1.96 TeV. AALTONEN 11AL looked for $\ell + \geq 4$j events and set upper limits on $\sigma(t'\overline{t}')$ as functions of $m_{t'}$.

[35] Based on 4.8 fb^{-1} of data in $p\overline{p}$ collisions at 1.96 TeV. AALTONEN 11O looked for $t'\overline{t}'$ production signal when t' decays into a top quark and X, an invisible particle, in $\ell + \not{E}_T$ + jets channel. No excess over the SM $t\overline{t}$ production gives the upper limit on $t'\overline{t}'$ production cross section as a function of $m_{t'}$ and m_X. The result is obtained for B($t' \to X\,t$) = 1.

[36] Based on 5.3 fb^{-1} of data in $p\overline{p}$ collisions at 1.96 TeV. ABAZOV 11Q looked for $\ell + \not{E}_T + \geq 4$j events and set upper limits on $\sigma(t'\overline{t}')$ as functions of $m_{t'}$.

[37] Searches for pair production of a new heavy top-like quark t' decaying to a W boson and another quark by fitting the observed spectrum of total transverse energy and reconstructed t' mass in the lepton + jets events.

[38] HUANG 08 reexamined the t' mass lower bound of 256 GeV obtained in AALTONEN 08H that assumes B($b' \to qZ$) = 1 for $q = u, c$ which does not hold when $m_{b'} < m_{t'} - m_W$ or the mixing $\sin^2(\theta_{bt'})$ is so tiny that the decay occurs outside of the vertex detector. Fig. 1 gives that lower bound on $m_{t'}$ in the plane of $\sin^2(\theta_{bt'})$ and $m_{b'}$.

>1350	95	[8] AABOUD	18AW	ATLS	$t'(5/3) \to t\,W^+$

[1] AAD 23AG based on 139 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. Pair production of vector-like top or b' is seached for in the mode $1\ell + \geq 4$j(≥ 1b-tagged) + $\not{E}_T$. The data are consistent with the SM background predictions and limits are obtained for different branching ratios.

[2] SIRUNYAN 19T based on 35.9 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. Signals are searched in the final states of t' pair production, with same-sign leptons (which come from a t' decay) or a single lepton (which comes from a W out of 4Ws), along with jets, and no excess over the SM expectation is found.

[3] AABOUD 18CE based on 36.1 fb^{-1} of proton-proton data taken at $\sqrt{s}$ = 13 TeV. Events including a same-sign lepton pair are used. The limit is for the pair-produced vector-like t'. With single t' production included, assuming $t'\,t\,W$ coupling of one, the limit is $m_{t'} > 1.6$ TeV.

[4] SIRUNYAN 17J based on 2.3 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. Signals are searched in the final states of t' pair production, with same-sign leptons (which come from a t' decay) or a single lepton (which comes from a W out of 4Ws), along with jets, and no excess over the SM expectation is found.

[5] AAD 15BY based on 20.3 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. Limit on $t'(5/3)$ in pair and single production assuming its coupling to Wt is equal to one. Used events containing $\geq 2\ell + \not{E}_T + \geq 2$j (≥ 1 b) and including a same-sign lepton pair.

[6] AAD 15Z based on 20.3 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. Used events with $\ell + \not{E}_T + \geq 6$j (≥ 1 b) and at least one pair of jets from weak boson decay, sensitive to the final state $b\overline{b}\,W^+\,W^-\,W^+\,W^-$.

[7] CHATRCHYAN 14T based on 19.5 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. Non-observation of anomaly in H_T distribution in the same-sign dilepton events leads to the limit when pair produced $t'(5/3)$ quark decays exclusively into t and W^+, resulting in the final state with $b\overline{b}\,W^+\,W^-\,W^+\,W^-$.

[8] AABOUD 18AW based on 36.1 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. Limit on $t'(5/3)$ in pair production assuming its coupling to Wt is equal to one. Lepton-plus-jets final state is used, characterized by $\ell + \not{E}_T$ + jets (≥ 1 b-tagged).

$t'(2/3)$ mass limits from single production in $p\overline{p}$ and pp collisions

[3] AAD	22G	ATLS	$t' \to Ht$, singlet t'	
[4] TUMASYAN	22X	CMS	$t' \to Zt$	

[1] AAD 16AV based on 20.3 fb^{-1} of pp data at $\sqrt{s}$ = 8 TeV. No significant excess over SM expectation is found in the search for a fully reconstructed vector-like t' in the mode $\ell + \not{E}_T + \geq 2j$ ($\geq 1b$). A veto on massive large-radius jets is used to reject the $t\overline{t}$ background.

[2] ABAZOV 11F based on 5.4 fb^{-1} of data in ppbar collisions at 1.96 TeV. It looked for single production of t' via the Z or E coupling to the first generation up or down quarks, respectively. Model independent cross section limits for the single production processes $p\overline{p} \to t'q \to (Wd)q$, and $p\overline{p} \to t'q \to (Zd)q$ are given in Figs. 3 and 4, respectively, and the mass limits are obtained for the model of ATRE 09 with degenerate bi-doublets of vector-like quarks.

[3] AAD 22G based on 139 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. No significant excess over SM expectation is found in the search for a vector-like t' in the Ht decay channel, where H and t are reconstructed as single jets. The mass range between 1.0 and 2.3 TeV is targeted and 95% CL limits on the production section times the decay branching fraction are set depending on the coupling and mass of t'.

[4] TUMASYAN 22X based on 137 fb^{-1} of pp data at $\sqrt{s}$ = 13 TeV. No significant excess over SM expectation is found in the search for a vector-like t' in the Zt decay channel, where Z decays to neutrinos and t decays hadronically. The 95% CL limits on the production section times the decay branching fraction are set depending on the coupling and mass of t'.

$t'(5/3)$ mass limits from single production in $p\overline{p}$ and pp collisions

Free Quark Searches

FREE QUARK SEARCHES

Quarks are fractionally charged particles, the constituents of hadrons, with charges 1/3 e or 2/3 e. The charge of every known charged system is an integer multiple of 1/3 e. Quantum Chromodynamics predicts that quarks cannot be observed as freely propagating particles, being confined inside hadrons or deconfined in quark-gluon plasma (QGP). We observe the top quark decaying as still free, because its lifetime is too short to allow its hadronization. Experiments have produced no evidence for free propagating quarks.

Reviews can be found in Refs. 1–5.

Quark Flux — Accelerator Searches

The definition of FLUX depends on the experiment

(a) is the ratio of measured free quarks to predicted free quarks if there is no "confinement."
(b) is the probability of fractional charge on nuclear fragments. Energy is in GeV/nucleon.
(c) is the 90%CL upper limit on fractionally-charged particles produced per interaction.
(d) is quarks per collision.
(e) is inclusive quark-production cross-section ratio to $\sigma(e^+e^-\to\mu^+\mu^-)$.
(f) is quark flux per charged particle.
(g) is the flux per ν-event.
(h) is quark yield per π^- yield.
(i) is 2-body exclusive quark-production cross-section ratio to $\sigma(e^+e^-\to\mu^+\mu^-)$.

[1] HUENTRUP 96 quote 95% CL limits for production of fragments with charge differing by as much as ±1/3 (in units of e) for charge $6 \leq Z \leq 10$.
[2] BUSKULIC 93C limits for inclusive quark production are more conservative if the ALEPH hadronic fragmentation function is assumed.
[3] CECCHINI 93 limit at 90%CL for $23/3 \leq Z \leq 40/3$, for 16A GeV O, 14.5A Si, and 200A S incident on Cu target. Other limits are 2.3×10^{-4} for $17/3 \leq Z \leq 20/3$ and 1.2×10^{-4} for $20/3 \leq Z \leq 23/3$.
[4] GHOSH 92 reports measurement of spallation fragment charge based on ionization in emulsion. Out of 650 measured tracks, 2 were consistent with charge $5e/3$, and 4 with $7e/3$.
[5] Hadronic quark.
[6] Leptonic quark.
[7] HE 91 limits are for charges of the form $N\pm1/3$ from 23/3 to 38/3, and correspond to cross-section limits of 380μb (Pb) and 320μb (Cu).
[8] The limits apply to projectile fragment charges of 17, 19, 20, 22, 23 in units of $e/3$.
[9] The limits apply to projectile fragment charges of 16, 17, 19, 20, 22, 23 in units of $e/3$.
[10] Flux limits and mass range depend on charge.
[11] Bound to nuclei.
[12] Quark lifetimes $> 1 \times 10^{-8}$ s.
[13] One candidate m <0.17 GeV.

Quark Flux — Cosmic Ray Searches

Shielding values followed with an asterisk indicate altitude in km. Shielding values not followed with an asterisk indicate sea level in kg/cm^2.

[1] ALEMANNO 22 uses data from the DAMPE satellite, with calorimetry and tracking to search for fractionally charged particles with $q = \pm 2/3e$ with a exposure time of 2.3×10^7 s.
[2] See AGNESE 15 Fig.6 for limits on vertical density as function of charge extending to $|q|/e < 1/10$.
[3] AMBROSIO 00C limit is below 11×10^{-15} for $0.25 < q/e < 0.5$, and is changing rapidly near q/e=2/3, where it is 2×10^{-14}.
[4] Distribution in celestial sphere was described as anisotropic.
[5] With telescope axis at zenith angle 40° to the south.
[6] Leptonic quarks.
[7] Lifetime $> 10^{-8}$ s; charge ±0.70, 0.68, 0.42; and mass >4.4, 4.8, and 20 GeV, respectively.
[8] Time delayed air shower search.
[9] Prompt air shower search.
[10] Also $e/4$ and $e/6$ charges.
[11] No events in subsequent experiments.

[1] 95% CL limit for fractional charge particles with $0.18e \leq |Q_{residual}| \leq 0.82e$ in total of 70.1 mg of silicone oil.

[2] 95% CL limit for particles with fractional charge $|Q_{residual}| > 0.16e$ in total of 17.4 mg of silicone oil.

[3] Also set limits for $Q = \pm e/6$.

[4] Note that in PHILLIPS 88 these authors report a subtle magnetic effect which could account for the apparent fractional charges.

[5] Limit inferred by JONES 77B.
